SKLL (pronounced “skull”) provides a number of utilities to make it simpler to run common scikit-learn experiments with pre-generated features.

There are two primary means of using SKLL: the run_experimenet script and the Python API.
1.1 Installation

SKLL can be installed via pip:

```
pip install skll
```

or via conda:

```
conda install -c conda-forge -c ets skll
```

It can also be downloaded directly from GitHub.

1.2 License

SKLL is distributed under the 3-clause BSD License.

1.3 Tutorial

Before doing anything below, you’ll want to install SKLL.
1.3.1 Workflow

In general, there are four steps to using SKLL:

1. Get some data in a *SKLL-compatible format*.
2. Create a small *configuration file* describing the machine learning experiment you would like to run.
3. Run that configuration file with *run_experiment*.
4. Examine the results of the experiment.

1.3.2 Titanic Example

Let’s see how we can apply the basic workflow above to a simple example using the Titanic: Machine Learning from Disaster data from Kaggle.

Get your data into the correct format

The first step is to get the Titanic data. We have already downloaded the data files from Kaggle and included them in the SKLL repository. Next, we need to get the files and process them to get them in the right shape.

The provided script, `make_titanic_example_data.py`, will split the train and test data files from Kaggle up into groups of related features and store them in dev, test, train, and train+dev subdirectories. The development set that gets created by the script is 20% of the data that was in the original training set, and train contains the other 80%.

Create a configuration file for the experiment

For this tutorial, we will refer to an “experiment” as having a single data set split into training and testing portions. As part of each experiment, we can train and test several models, either simultaneously or sequentially, depending whether we’re using GridMap or not. This will be described in more detail later on, when we are ready to run our experiment.

You can consult the *full list of learners currently available* in SKLL to get an idea for the things you can do. As part of this tutorial, we will use the following classifiers:

- Decision Tree
- Multinomial Naïve Bayes
- Random Forest
- Support Vector Machine
Let’s take a look at the options specified in `titanic/evaluate_tuned.cfg`. Here, we are only going to train a model and evaluate its performance on the development set, because in the General section, task is set to evaluate. We will explore the other options for task later.

In the Input section, we have specified relative paths to the training and testing directories via the `train_directory` and `test_directory` settings respectively. `featuresets` indicates the name of both the training and testing files. `learners` must always be specified in between `[ ]` brackets, even if you only want to use one learner. This is similar to the `featuresets` option, which requires two sets of brackets, since multiple sets of different-yet-related features can be provided. We will keep our examples simple, however, and only use one set of features per experiment. The `label_col` and `id_col` settings specify the columns in the CSV files that specify the class labels and instances IDs for each example.

The Tuning section defines how we want our model to be tuned. Setting `grid_search` to `True` here employs scikit-learn’s GridSearchCV class, which is an implementation of the standard, brute-force approach to hyperparameter optimization.
objectives refers to the desired objective functions; here, accuracy will optimize for overall accuracy. You can see a list of all the available objective functions here.

In the Output section, we first define the additional evaluation metrics we want to compute in addition to the tuning objective via the metrics option. The other options are directories where you’d like all of the relevant output from your experiment to go. results refers to the results of the experiment in both human-readable and JSON forms. log specifies where to put log files containing any status, warning, or error messages generated during model training and evaluation. predictions refers to where to store the individual predictions generated for the test set. models is for specifying a directory to serialize the trained models.

Running your configuration file through run_experiment

Getting your experiment running is the simplest part of using SKLL, you just need to type the following into a terminal:

```
$ run_experiment titanic/evaluate_tuned.cfg
```

That should produce output like:

```
2020-03-10 14:25:23,596 - Titanic_Evaluate_Tuned_family.csv+misc. → csv+socioeconomic.csv+vitals.csv_RandomForestClassifier - INFO - Task: evaluate
2020-03-10 14:25:23,596 - Titanic_Evaluate_Tuned_family.csv+misc. → csv+socioeconomic.csv+vitals.csv_RandomForestClassifier - INFO - Training on train, Test on dev, feature set ['family.csv', 'misc.csv', 'socioeconomic.csv', 'vitals.csv'] ...
Loading /Users/nmadnani/work/skll/examples/titanic/train/family.csv... done
Loading /Users/nmadnani/work/skll/examples/titanic/train/misc.csv... done
Loading /Users/nmadnani/work/skll/examples/titanic/train/socioeconomic.csv... done
Loading /Users/nmadnani/work/skll/examples/titanic/train/vitals.csv... done
Loading /Users/nmadnani/work/skll/examples/titanic/dev/family.csv... done
Loading /Users/nmadnani/work/skll/examples/titanic/dev/misc.csv... done
Loading /Users/nmadnani/work/skll/examples/titanic/dev/socioeconomic.csv... done
Loading /Users/nmadnani/work/skll/examples/titanic/dev/vitals.csv... done
2020-03-10 14:25:23,662 - Titanic_Evaluate_Tuned_family.csv+misc. → csv+socioeconomic.csv+vitals.csv_RandomForestClassifier - INFO - Featurizing and training new RandomForestClassifier model
```
Training data will be shuffled to randomize grid search folds. Shuffling may yield different results compared to scikit-learn.

Best accuracy grid search score: 0.798

Hyperparameters: bootstrap: True, ccp_alpha: 0.0, class_weight: None, criterion: gini, max_depth: 5, max_features: auto, max_leaf_nodes: None, max_samples: None, min_impurity_decrease: 0.0, min_impurity_split: None, min_samples_leaf: 1, min_samples_split: 2, min_weight_fraction_leaf: 0.0, n_estimators: 500, n_jobs: None, oob_score: False, random_state: 123456789, verbose: 0, warm_start: False

Evaluating predictions using probabilities for the positive class to compute "roc_auc" for evaluation.
We could squelch the warnings about shuffling by setting `shuffle` to `True` in the `Input` section.

The reason we see the loading messages repeated is that we are running the different learners sequentially, whereas SKLL is designed to take advantage of a cluster to execute everything in parallel via GridMap.

**Examine the results**

As a result of running our experiment, there will be a whole host of files in our `results` directory. They can be broken down into three types of files:

1. `.results` files, which contain a human-readable summary of the experiment, complete with confusion matrix.
2. `.results.json` files, which contain all of the same information as the `.results` files, but in a format more well-suited to automated processing.
3. A summary `.tsv` file, which contains all of the information in all of the `.results.json` files with one line per file. This is very nice if you’re trying many different learners and want to compare their performance. If you do additional experiments later (with a different config file), but would like one giant summary file, you can use the `summarize_results` command.
An example of a human-readable results file for our Titanic experiment is:

```
Experiment Name: Titanic_Evaluate_Tuned
SKLL Version: 2.1
Training Set: train
Training Set Size: 569
Test Set: dev
Test Set Size: 143
Shuffle: False
Feature Set: ["family.csv", "misc.csv", "socioeconomic.csv", "vitals.csv"]
Learner: RandomForestClassifier
Task: evaluate
Feature Scaling: none
Grid Search: True
Grid Search Folds: 3
Grid Objective Function: accuracy
Additional Evaluation Metrics: ['roc_auc']
Scikit-learn Version: 0.22.2.post1

1.3.3 IRIS Example on Binder

If you prefer using an interactive Jupyter notebook to learn about SKLL, you can do so by clicking the launch button below.

1.4 Running Experiments

1.4.1 General Workflow

To run your own SKLL experiments via the command line, the following general workflow is recommended.

Get your data into the correct format

SKLL can work with several common data formats, all of which are described here.

If you need to convert between any of the supported formats, because, for example, you would like to create a single data file that will work both with SKLL and Weka (or some other external tool), the `skll_convert` script can help you out. It is as easy as:

```
$ skll_convert examples/titanic/train/family.csv examples/titanic/
    train/family.arff
```

Create sparse feature files, if necessary

`skll_convert` can also create sparse data files in `.jsonlines`, `.libsvm`, `.megam`, or `.ndj` formats. This is very useful for saving disk space and memory when you have a large data set with mostly zero-valued features.

Set up training and testing directories/files

At a minimum, you will probably want to work with a training set and a testing set. If you have multiple feature files that you would like SKLL to join together for you automatically, you will need to create feature files with the exact same names and store them in training and testing directories. You can specify these directories in your config file using `train_directory` and `test_directory`. The list of files is specified using the `featuresets` setting.

If you’re conducting a simpler experiment, where you have a single training file with all of your features and a similar single testing file, you should use the `train_file` and `test_file` settings in your config file.

Note: If you would like to split an existing file up into a training set and a testing set, you can employ the `filter_features` utility script to select instances you would like to include in each file.
Create an experiment configuration file

You saw a basic configuration file in the tutorial. For your own experiment, you will need to refer to the Configuration file fields section.

Run configuration file through run_experiment

There are a few meta-options for experiments that are specified directly to the run_experiment command rather than in a configuration file. For example, if you would like to run an ablation experiment, which conducts repeated experiments using different combinations of the features in your config, you should use the run_experiment --ablation option. A complete list of options is available here.

Next, we describe the numerous file formats that SKLL supports for reading in features.

1.4.2 Feature files

SKLL supports the following feature file formats:

arf

The same file format used by Weka with the following added restrictions:

- Only simple numeric, string, and nominal values are supported.
- Nominal values are converted to strings.
- If the data has instance IDs, there should be an attribute with the name specified by id_col in the Input section of the configuration file you create for your experiment. This defaults to id. If there is no such attribute, IDs will be generated automatically.
- If the data is labelled, there must be an attribute with the name specified by label_col in the Input section of the configuration file you create for your experiment. This defaults to y. This must also be the final attribute listed (like in Weka).

csv/tsv

A simple comma or tab-delimited format. SKLL underlyingly uses [pandas](https://pandas.pydata.org) to read these files which is extremely fast but at the cost of some extra memory consumption.

When using this file format, the following restrictions apply:

- If the data is labelled, there must be a column with the name specified by label_col in the Input section of the configuration file you create for your experiment. This defaults to y.
- If the data has instance IDs, there should be a column with the name specified by id_col in the Input section of the configuration file you create for your experiment. This defaults to id. If there is no such column, IDs will be generated automatically.
• All other columns contain feature values, and every feature value must be specified (making this a poor choice for sparse data).

**Warning:**

1. SKLL will raise an error if there are blank values in any of the columns. You must either drop all rows with blank values in any column or replace the blanks with a value you specify. To drop or replace via the command line, use the `filter_features` script. You can also drop/replace via the SKLL Reader API, specifically `skll.data.readers.CSVReader` and `skll.data.readers.TSVReader`.

2. Dropping blanks will drop all rows with blanks in any of the columns. If you care only about some of the columns in the file and do not want to rows to be dropped due to blanks in the other columns, you should remove the columns you do not care about before dropping the blanks. For example, consider a hypothetical file `in.csv` that contains feature columns named A through G with the IDs stored in a column named ID and the labels stored in a column named CLASS. You only care about columns A, C, and F and want to drop all rows in the file that have blanks in any of these 3 columns but do not want to lose data due to there being blanks in any of the other columns. On the command line, you can run the following two commands:

   ```bash
   $ filter_features -f A C F --id_col ID --label_col CLASS in.csv temp.csv
   $ filter_features --id_col ID --label_col CLASS --drop_blanks temp.csv out.csv
   ```

   If you are using the SKLL Reader API, you can accomplish the same in a single step by also passing using the keyword argument `pandas_kwargs` when instantiating either a `skll.data.readers.CSVReader` or a `skll.data.readers.TSVReader`. For our example:

   ```python
   r = CSVReader.for_path('/path/to/in.csv',
                        label_col='CLASS',
                        id_col='ID',
                        drop_blanks=True,
                        pandas_kwargs={'usecols': ['A',
                                                  'C', 'F', 'ID', 'CLASS']})
   fs = r.read()
   ```

Make sure to include the ID and label columns in the `usecols` list otherwise pandas will drop them too.

**jsonlines/ndj (Recommended)**

A twist on the JSON format where every line is a either JSON dictionary (the entire contents of a normal JSON file), or a comment line starting with `//`. Each dictionary is expected to contain the
following keys:

- **y**: The class label.
- **x**: A dictionary of feature values.
- **id**: An optional instance ID.

This is the preferred file format for SKLL, as it is sparse and can be slightly faster to load than other formats.

**libsvm**

While we can process the standard input file format supported by LibSVM, LibLinear, and SVM-Light, we also support specifying extra metadata usually missing from the format in comments at the of each line. The comments are not mandatory, but without them, your labels and features will not have names. The comment is structured as follows:

```
ID | 1=ClassX | 1=FeatureA 2=FeatureB
```

The entire format would like this:

```
2 1:2.0 3:8.1 # Example1 | 2=ClassY | 1=FeatureA 3=FeatureC
1 5:7.0 6:19.1 # Example2 | 1=ClassX | 5=FeatureE 6=FeatureF
```

**Note:** IDs, labels, and feature names cannot contain the following characters: | # =

**megam**

An expanded form of the input format for the MegaM classification package with the -fvals switch.

The basic format is:

```
# Instance1
CLASS1 F0 2.5 F1 3 FEATURE_2 -152000
# Instance2
CLASS2 F1 7.524
```

where the optional comments before each instance specify the ID for the following line, class names are separated from feature-value pairs with a tab, and feature-value pairs are separated by spaces. Any omitted features for a given instance are assumed to be zero, so this format is handy when dealing with sparse data. We also include several utility scripts for converting to/from this MegaM format and for adding/removing features from the files.
1.4.3 Configuration file fields

The experiment configuration files that run_experiment accepts are standard Python configuration files that are similar in format to Windows INI files.¹ There are four expected sections in a configuration file: General, Input, Tuning, and Output. A detailed description of each field in each section is provided below, but to summarize:

- If you want to do cross-validation, specify a path to training feature files, and set task to cross_validate. Please note that the cross-validation currently uses StratifiedKFold. You also can optionally use predetermined folds with the folds_file setting.

  Note: When using classifiers, SKLL will automatically reduce the number of cross-validation folds to be the same as the minimum number of examples for any of the classes in the training data.

- If you want to train a model and evaluate it on some data, specify a training location, a test location, and a directory to store results, and set task to evaluate.

- If you want to just train a model and generate predictions, specify a training location, a test location, and set task to predict.

- If you want to just train a model, specify a training location, and set task to train.

- If you want to generate a learning curve for your data, specify a training location and set task to learning_curve. The learning curve is generated using essentially the same underlying process as in scikit-learn except that the SKLL feature pre-processing pipeline is used while training the various models and computing the scores.

  Note: Ideally, one would first do cross-validation experiments with grid search and/or ablation and get a well-performing set of features and hyper-parameters for a set of learners. Then, one would explicitly specify those features (via featuresets) and hyper-parameters (via fixed_parameters) in the config file for the learning curve and explore the impact of the size of the training data.

- A list of classifiers/regressors to try on your feature files is required.

Example configuration files are available here under the boston, iris, and titanic sub-directories.

General

Both fields in the General section are required.

¹ We are considering adding support for YAML configuration files in the future, but we have not added this functionality yet.
experiment_name

A string used to identify this particular experiment configuration. When generating result summary files, this name helps prevent overwriting previous summaries.

task

What types of experiment we’re trying to run. Valid options are: cross_validate, evaluate, predict, train, learning_curve.

Input

The Input section must specify the machine learners to use via the learners field as well as the data and features to be used when training the model. This can be done by specifying either (a) train_file in which case all of the features in the file will be used, or (b) train_directory along with featuresets.

learners

List of scikit-learn models to be used in the experiment. Acceptable values are described below. Custom learners can also be specified. See custom_learner_path.

Classifiers:

- **AdaBoostClassifier**: AdaBoost Classification. Note that the default base estimator is a DecisionTreeClassifier. A different base estimator can be used by specifying a base_estimator fixed parameter in the fixed_parameters list. The following additional base estimators are supported: MultinomialNB, SGDClassifier, and SVC. Note that the last two base require setting an additional algorithm fixed parameter with the value 'SAMME'.
- **DummyClassifier**: Simple rule-based Classification
- **DecisionTreeClassifier**: Decision Tree Classification
- **GradientBoostingClassifier**: Gradient Boosting Classification
- **KNeighborsClassifier**: K-Nearest Neighbors Classification
- **LinearSVC**: Support Vector Classification using LibLinear
- **LogisticRegression**: Logistic Regression Classification using LibLinear
- **MLPClassifier**: Multi-layer Perceptron Classification
- **MultinomialNB**: Multinomial Naive Bayes Classification
• **RandomForestClassifier**: Random Forest Classification
• **RidgeClassifier**: Classification using Ridge Regression
• **SGDClassifier**: Stochastic Gradient Descent Classification
• **SVC**: Support Vector Classification using LibSVM

**Regressors:**

• **AdaBoostRegressor**: AdaBoost Regression. Note that the default base estimator is a `DecisionTreeRegressor`. A different base estimator can be used by specifying a `base_estimator` fixed parameter in the `fixed_parameters` list. The following additional base estimators are supported: `SGDRegressor`, and `SVR`.

• **BayesianRidge**: Bayesian Ridge Regression
• **DecisionTreeRegressor**: Decision Tree Regressor
• **DummyRegressor**: Simple Rule-based Regression
• **ElasticNet**: ElasticNet Regression
• **GradientBoostingRegressor**: Gradient Boosting Regressor
• **HuberRegressor**: Huber Regression
• **KNeighborsRegressor**: K-Nearest Neighbors Regression
• **Lars**: Least Angle Regression
• **Lasso**: Lasso Regression
• **LinearRegression**: Linear Regression
• **LinearSVR**: Support Vector Regression using LibLinear
• **MLPRegressor**: Multi-layer Perceptron Regression
• **RandomForestRegressor**: Random Forest Regression
• **RANSACRegressor**: RANdom SAMple Consensus Regression. Note that the default base estimator is a `LinearRegression`. A different base regressor can be used by specifying a `base_estimator` fixed parameter in the `fixed_parameters` list.

• **Ridge**: Ridge Regression
• **SGDRegressor**: Stochastic Gradient Descent Regression
• **SVR**: Support Vector Regression using LibSVM
• **TheilSenRegressor**: Theil-Sen Regression
For all regressors, you can also prepend `Rescaled` to the beginning of the full name (e.g., `RescaledSVR`) to get a version of the regressor where predictions are rescaled and constrained to better match the training set.

**featuresets**

List of lists of prefixes for the files containing the features you would like to train/test on. Each list will end up being a job. IDs are required to be the same in all of the feature files, and a `ValueError` will be raised if this is not the case. Cannot be used in combination with `train_file` or `test_file`.

**Note:** If specifying `train_directory` or `test_directory`, `featuresets` is required.

**train_file**

Path to a file containing the features to train on. Cannot be used in combination with `featuresets`, `train_directory`, or `test_directory`.

**Note:** If `train_file` is not specified, `train_directory` must be.

**train_directory**

Path to directory containing training data files. There must be a file for each featureset. Cannot be used in combination with `train_file` or `test_file`.

**Note:** If `train_directory` is not specified, `train_file` must be.

The following is a list of the other optional fields in this section in alphabetical order.

**class_map (Optional)**

If you would like to collapse several labels into one, or otherwise modify your labels (without modifying your original feature files), you can specify a dictionary mapping from new class labels to lists of original class labels. For example, if you wanted to collapse the labels beagle and dachshund into a dog class, you would specify the following for `class_map:`
{'dog': ['beagle', 'dachsund']}

Any labels not included in the dictionary will be left untouched.

One other use case for `class_map` is to deal with classification labels that would be converted to float improperly. All Reader sub-classes use the `skll.data.readers.safe_float` function internally to read labels. This function tries to convert a single label first to int, then to float. If neither conversion is possible, the label remains a str. Thus, care must be taken to ensure that labels do not get converted in unexpected ways. For example, consider the situation where there are classification labels that are a mixture of int-converting and float-converting labels:

```python
import numpy as np
from skll.data.readers import safe_float
np.array([safe_float(x) for x in ['2', '2.2', '2.21']])  # array([2. , 2.2, 2.21])
```

The labels will all be converted to floats and any classification model generated with this data will predict labels such as 2.0, 2.2, etc., not str values that exactly match the input labels, as might be expected. `class_map` could be used to map the original labels to new values that do not have the same characteristics.

**custom_learner_path (Optional)**

Path to a .py file that defines a custom learner. This file will be imported dynamically. This is only required if a custom learner is specified in the list of `learners`.

All Custom learners must implement the `fit` and `predict` methods. Custom classifiers must either (a) inherit from an existing scikit-learn classifier, or (b) inherit from both `sklearn.base.BaseEstimator. and from sklearn.base.ClassifierMixin`

Similarly, Custom regressors must either (a) inherit from an existing scikit-learn regressor, or (b) inherit from both `sklearn.base.BaseEstimator. and from sklearn.base.RegressorMixin`

Learners that require dense matrices should implement a method `requires_dense` that returns True.

**feature_hasher (Optional)**

If “true”, this enables a high-speed, low-memory vectorizer that uses feature hashing for converting feature dictionaries into NumPy arrays instead of using a DictVectorizer. This flag will drastically reduce memory consumption for data sets with a large number of features. If enabled, the user should also specify the number of features in the `hasher_features` field. For additional information see the scikit-learn documentation.
**Warning:** Due to the way SKLL experiments are architected, if the features for an experiment are spread across multiple files on disk, feature hashing will be applied to each file separately. For example, if you have F feature files and you choose H as the number of hashed features (via `hasher_features`), you will end up with \( F \times H \) features in the end. If this is not the desired behavior, use the `join_features` utility script to combine all feature files into a single file before running the experiment.

**feature_scaling (Optional)**

Whether to scale features by their mean and/or their standard deviation. If you scale by mean, your data will automatically be converted to dense, so use caution when you have a very large dataset. Valid options are:

- **none** Perform no feature scaling at all.
- **with_std** Scale feature values by their standard deviation.
- **with_mean** Center features by subtracting their mean.
- **both** Perform both centering and scaling.

Defaults to none.

**featureset_names (Optional)**

Optional list of names for the feature sets. If omitted, then the prefixes will be munged together to make names.

**folds_file (Optional)**

Path to a csv file specifying the mapping of instances in the training data to folds. This can be specified when the `task` is either `train` or `cross_validate`. For the `train` task, if `grid_search` is True, this file, if specified, will be used to define the cross-validation used for the grid search (leave one fold ID out at a time). Otherwise, it will be ignored.

For the `cross_validate` task, this file will be used to define the outer cross-validation loop and, if `grid_search` is True, also for the inner grid-search cross-validation loop. If the goal of specifying the folds file is to ensure that the model does not learn to differentiate based on a confound: e.g. the data from the same person is always in the same fold, it makes sense to keep the same folds for both the outer and the inner cross-validation loops.

However, sometimes the goal of specifying the folds file is simply for the purpose of comparison to another existing experiment or another context in which maintaining the constitution of
the folds in the inner grid-search loop is not required. In this case, users may set the parameter `use_folds_file_for_grid_search` to `False` which will then direct the inner grid-search cross-validation loop to simply use the number specified via `grid_search_folds` instead of using the folds file. This will likely lead to shorter execution times as well depending on how many folds are in the folds file and the value of `grid_search_folds`.

The format of this file must be as follows: the first row must be a header. This header row is ignored, so it doesn’t matter what the header row contains, but it must be there. If there is no header row, whatever row is in its place will be ignored. The first column should consist of training set IDs and the second should be a string for the fold ID (e.g., 1 through 5, A through D, etc.). If specified, the CV and grid search will leave one fold ID out at a time.\(^2\)

**fixed_parameters (Optional)**

List of dictionaries containing parameters you want to have fixed for each learner in `learners` list. Any empty ones will be ignored (and the defaults will be used). If `grid_search (Optional)` is `True`, there is a potential for conflict with specified/default parameter grids and fixed parameters.

The default fixed parameters (beyond those that scikit-learn sets) are:

**AdaBoostClassifier and AdaBoostRegressor**

```python
{'n_estimators': 500, 'random_state': 123456789}
```

**DecisionTreeClassifier and DecisionTreeRegressor**

```python
{'random_state': 123456789}
```

**DummyClassifier**

```python
{'random_state': 123456789}
```

**ElasticNet**

```python
{'random_state': 123456789}
```

**GradientBoostingClassifier and GradientBoostingRegressor**

```python
{'n_estimators': 500, 'random_state': 123456789}
```

**Lasso:**

```python
{'random_state': 123456789}
```

**LinearSVC and LinearSVR**

\(^2\) K-1 folds will be used for grid search within CV, so there should be at least 3 fold IDs.
LogisticRegression

{'max_iter': 1000, 'multi_class': 'auto', 'random_state': 123456789, 'solver': 'liblinear'}

**Note:** The regularization penalty used by default is "l2". However, "l1", "elasticnet", and "none" (no regularization) are also available. There is a dependency between the penalty and the solver. For example, the "elasticnet" penalty can only be used in conjunction with the "saga" solver. See more information in the scikit-learn documentation here.

MLPClassifier and MLPRegressor:

{'learning_rate': 'invscaling', 'max_iter': 500}

RandomForestClassifier and RandomForestRegressor

{'n_estimators': 500, 'random_state': 123456789}

RANSACRegressor

{'loss': 'squared_loss', 'random_state': 123456789}

Ridge and RidgeClassifier

{'random_state': 123456789}

SVC and SVR

{'cache_size': 1000, 'gamma': 'scale'}

SGDClassifier

{'loss': 'log', 'max_iter': 1000, 'random_state': 123456789, 'tol': 1e-3}

SGDRegressor

{'max_iter': 1000, 'random_state': 123456789, 'tol': 1e-3}

TheilSenRegressor

1.4. Running Experiments
Note:

The `fixed_parameters` field offers us a way to deal with imbalanced data sets by using the parameter `class_weight` for the following classifiers: `DecisionTreeClassifier`, `LogisticRegression`, `LinearSVC`, `RandomForestClassifier`, `RidgeClassifier`, `SGDClassifier`, and `SVC`.

Two possible options are available. The first one is `balanced`, which automatically adjusts weights inversely proportional to class frequencies, as shown in the following code:

```
{'class_weight': 'balanced'}
```

The second option allows you to assign a specific weight per each class. The default weight per class is 1. For example:

```
{'class_weight': {1: 10}}
```

Additional examples and information can be seen here.

**hasher_features (Optional)**

The number of features used by the `FeatureHasher` if the `feature_hasher` flag is enabled.

**Note:** To avoid collisions, you should always use the power of two larger than the number of features in the data set for this setting. For example, if you had 17 features, you would want to set the flag to 32.

**id_col (Optional)**

If you’re using ARFF, CSV, or TSV files, the IDs for each instance are assumed to be in a column with this name. If no column with this name is found, the IDs are generated automatically. Defaults to `id`.

**ids_to_floats (Optional)**

If you have a dataset with lots of examples, and your input files have IDs that look like numbers (can be converted by float()), then setting this to True will save you some memory by storing IDs
as floats. Note that this will cause IDs to be printed as floats in prediction files (e.g., 4.0 instead of 4 or 0004 or 4.000).

**label_col (Optional)**

If you’re using ARFF, CSV, or TSV files, the class labels for each instance are assumed to be in a column with this name. If no column with this name is found, the data is assumed to be unlabelled. Defaults to y. For ARFF files only, this must also be the final column to count as the label (for compatibility with Weka).

**learning_curve_cv_folds_list (Optional)**

List of integers specifying the number of folds to use for cross-validation at each point of the learning curve (training size), one per learner. For example, specifying ["SVC", "LogisticRegression"] for learners and specifying [10, 100] for learning_curve_cv_folds_list will tell SKLL to use 10 cross-validation folds at each point of the SVC curve and 100 cross-validation folds at each point of the logistic regression curve. Although more folds will generally yield more reliable results, smaller number of folds may be better for learners that are slow to train. Defaults to 10 for each learner.

**learning_curve_train_sizes (Optional)**

List of floats or integers representing relative or absolute numbers of training examples that will be used to generate the learning curve respectively. If the type is float, it is regarded as a fraction of the maximum size of the training set (that is determined by the selected validation method), i.e. it has to be within (0, 1]. Otherwise it is interpreted as absolute sizes of the training sets. Note that for classification the number of samples usually has to be big enough to contain at least one sample from each class. Defaults to [0.1, 0.325, 0.55, 0.775, 1.0].

**num_cv_folds (Optional)**

The number of folds to use for cross validation. Defaults to 10.

**random_folds (Optional)**

Whether to use random folds for cross-validation. Defaults to False.
sampler *(Optional)*

Whether to use a feature sampler that performs non-linear transformations of the input, which can serve as a basis for linear classification or other algorithms. Valid options are: Nystroem, RBFSampler, SkewedChi2Sampler, and AdditiveChi2Sampler. For additional information see the scikit-learn documentation.

**Note:** Using a feature sampler with the MultinomialNB learner is not allowed since it cannot handle negative feature values.

sampler_parameters *(Optional)*

dict containing parameters you want to have fixed for the sampler. Any empty ones will be ignored (and the defaults will be used).

The default fixed parameters (beyond those that scikit-learn sets) are:

**Nystroem**

```python
dict({'random_state': 123456789})
```

**RBFSampler**

```python
dict({'random_state': 123456789})
```

**SkewedChi2Sampler**

```python
dict({'random_state': 123456789})
```

shuffle *(Optional)*

If True, shuffle the examples in the training data before using them for learning. This happens automatically when doing a grid search but it might be useful in other scenarios as well, e.g., online learning. Defaults to False.

suffix *(Optional)*

The file format the training/test files are in. Valid option are `.arff`, `.csv`, `.jsonlines`, `.libsvm`, `.megam`, `.ndj`, and `.tsv`. 

If you omit this field, it is assumed that the “prefixes” listed in featuresets are actually complete filenames. This can be useful if you have feature files that are all in different formats that you would like to combine.

**test_file (Optional)**

Path to a file containing the features to test on. Cannot be used in combination with featuresets, train_directory, or test_directory.

**test_directory (Optional)**

Path to directory containing test data files. There must be a file for each featureset. Cannot be used in combination with train_file or test_file.

### Tuning

Generally, in this section, you would specify fields that pertain to the hyperparameter tuning for each learner. The most common required field is objectives although it may also be optional in certain circumstances.

**objectives**

A list of one or more metrics to use as objective functions for tuning the learner hyperparameters via grid search. Note that objectives is required by default in most cases unless (a) grid_search is explicitly set to False or (b) the task is learning_curve. For (a), any specified objectives are ignored. For (b), specifying objectives will raise an exception.

Available metrics are:

**Classification:** The following objectives can be used for classification problems although some are restricted by problem type (binary/multiclass), types of labels (integers/floats/strings), and whether they are contiguous (if integers). Please read carefully.

Note: When doing classification, SKLL internally sorts and maps all the class labels in the data and maps them to integers which can be thought of class indices. This happens irrespective of the data type of the original labels. For example, if your data has the labels ['A', 'B', 'C'], SKLL will map them to the indices [0, 1, 2] respectively. It will do the same if you have integer labels ([1, 2, 3]) or floating point ones ([1.0, 1.1, 1.2]). All of the tuning objectives are computed using these integer indices rather than the original class labels. This is why some metrics only make sense in certain scenarios. For example, SKLL only allows using weighted...
kappa metrics as tuning objectives if the original class labels are contiguous integers, e.g., \([1, 2, 3]\) or \([4, 5, 6]\) – or even integer-like floats (e.g., \([1.0, 2.0, 3.0]\), but not \([1.0, 1.1, 1.2]\)).

- **accuracy**: Overall accuracy
- **average_precision**: Area under PR curve. To use this metric, `probability` must be set to `True`. (*Binary classification only*).
- **balanced_accuracy**: A version of accuracy specifically designed for imbalanced binary and multi-class scenarios.
- **f1**: The default scikit-learn \(F_1\) score (\(F_1\) of the positive class for binary classification, or the weighted average \(F_1\) for multiclass classification)
- **f1_score_micro**: Micro-averaged \(F_1\) score
- **f1_score_macro**: Macro-averaged \(F_1\) score
- **f1_score_weighted**: Weighted average \(F_1\) score
- **f1_score_least_frequent**: \(F_1\) score of the least frequent class. The least frequent class may vary from fold to fold for certain data distributions.
- **kendall_tau**: Kendall’s tau. For binary classification and with `probability` set to `True`, the probabilities for the positive class will be used to compute the correlation values. In all other cases, the labels are used. (*Integer labels only*).
- **linear_weighted_kappa**: Linear weighted kappa. (*Contiguous integer labels only*).
- **lwk_off_by_one**: Same as `linear_weighted_kappa`, but all ranking differences are discounted by one. (*Contiguous integer labels only*).
- **neg_log_loss**: The negative of the classification log loss. Since scikit-learn recommends using negated loss functions as scorer functions, SKLL does the same for the sake of consistency. To use this metric, `probability` must be set to `True`.
- **pearson**: Pearson correlation. For binary classification and with `probability` set to `True`, the probabilities for the positive class will be used to compute the correlation values. In all other cases, the labels are used. (*Integer labels only*).
- **precision**: Precision
- **quadratic_weighted_kappa**: Quadratic weighted kappa. (*Contiguous integer labels only*).
- **qwk_off_by_one**: Same as `quadratic_weighted_kappa`, but all ranking differences are discounted by one. (*Contiguous integer labels only*).
- **recall**: Recall
• **roc_auc**: Area under ROC curve. To use this metric, `probability` must be set to `True`. (*Binary classification only*).

• **spearman**: Spearman rank-correlation. For binary classification and with `probability` set to `True`, the probabilities for the positive class will be used to compute the correlation values. In all other cases, the labels are used. (*Integer labels only*).

• **unweighted_kappa**: Unweighted Cohen’s kappa.

• **uwk_off_by_one**: Same as `unweighted_kappa`, but all ranking differences are discounted by one. In other words, a ranking of 1 and a ranking of 2 would be considered equal.

**Regression**: The following objectives can be used for regression problems.

• **explained_variance**: A score indicating how much of the variance in the given data can be by the model.

• **kendall_tau**: Kendall’s tau

• **linear_weighted_kappa**: Linear weighted kappa (any floating point values are rounded to ints)

• **lwk_off_by_one**: Same as `linear_weighted_kappa`, but all ranking differences are discounted by one.

• **max_error**: The maximum residual error.

• **neg_mean_absolute_error**: The negative of the mean absolute error regression loss. Since scikit-learn recommends using negated loss functions as scorer functions, SKLL does the same for the sake of consistency.

• **neg_mean_squared_error**: The negative of the mean squared error regression loss. Since scikit-learn recommends using negated loss functions as scorer functions, SKLL does the same for the sake of consistency.

• **pearson**: Pearson correlation

• **quadratic_weighted_kappa**: Quadratic weighted kappa (any floating point values are rounded to ints)

• **qwk_off_by_one**: Same as `quadratic_weighted_kappa`, but all ranking differences are discounted by one.

• **r2**: R2

• **spearman**: Spearman rank-correlation

• **unweighted_kappa**: Unweighted Cohen’s kappa (any floating point values are rounded to ints)
• **uwk_off_by_one**: Same as unweighted_kappa, but all ranking differences are discounted by one. In other words, a ranking of 1 and a ranking of 2 would be considered equal.

The following is a list of the other optional fields in this section in alphabetical order.

**grid_search (Optional)**

Whether or not to perform grid search to find optimal parameters for the learner. Defaults to `True` since optimizing model hyperparameters almost always leads to better performance. Note that for the `learning_curve` task, grid search is not allowed and setting it to `True` will generate a warning and be ignored.

**Note:**

1. In versions of SKLL before v2.0, this option was set to `False` by default but that was changed since the benefits of hyperparameter tuning significantly outweigh the cost in terms of model fitting time. Instead, SKLL users must explicitly opt out of hyperparameter tuning if they so desire.

2. Although SKLL only uses the combination of hyperparameters in the grid that maximizes the grid search objective, the results for all other points on the grid that were tried are also available. See the `grid_search_cv_results` attribute in the `.results.json` file.

**grid_search_folds (Optional)**

The number of folds to use for grid search. Defaults to 3.

**grid_search_jobs (Optional)**

Number of folds to run in parallel when using grid search. Defaults to number of grid search folds.

**min_feature_count (Optional)**

The minimum number of examples for which the value of a feature must be nonzero to be included in the model. Defaults to 1.

**param_grids (Optional)**

List of parameter grids to search for each learner. Each parameter grid should be a list of dictionaries mapping from strings to lists of parameter values. When you specify an empty list for a learner,
the default parameter grid for that learner will be searched.

The default parameter grids for each learner are:

### AdaBoostClassifier and AdaBoostRegressor

```python
[{'learning_rate': [0.01, 0.1, 1.0, 10.0, 100.0]})
```

### BayesianRidge

```python
[{'alpha_1': [1e-6, 1e-4, 1e-2, 1, 10],
 'alpha_2': [1e-6, 1e-4, 1e-2, 1, 10],
 'lambda_1': [1e-6, 1e-4, 1e-2, 1, 10],
 'lambda_2': [1e-6, 1e-4, 1e-2, 1, 10]})
```

### DecisionTreeClassifier and DecisionTreeRegressor

```python
[{'max_features': ['auto', None]})
```

### ElasticNet

```python
[{'alpha': [0.01, 0.1, 1.0, 10.0, 100.0]})
```

### GradientBoostingClassifier and GradientBoostingRegressor

```python
[{'max_depth': [1, 3, 5]})
```

### HuberRegressor

```python
[{'epsilon': [1.05, 1.35, 1.5, 2.0, 2.5, 5.0],
 'alpha': [1e-4, 1e-3, 1e-3, 1e-1, 1, 10, 100, 1000]})
```

### KNeighborsClassifier and KNeighborsRegressor

```python
[{'n_neighbors': [1, 5, 10, 100],
 'weights': ['uniform', 'distance']})
```

### Lasso

```python
[{'alpha': [0.01, 0.1, 1.0, 10.0, 100.0]})
```

### LinearSVC

```python
[{'C': [0.01, 0.1, 1.0, 10.0, 100.0]})
```

### LogisticRegression

```python
[{'C': [0.01, 0.1, 1.0, 10.0, 100.0]})
```
MLPClassifier and MLPRegressor:

```
[{'activation': ['logistic', 'tanh', 'relu'],
  'alpha': [1e-4, 1e-3, 1e-3, 1e-1, 1],
  'learning_rate_init': [0.001, 0.01, 0.1]}],
```

MultinomialNB

```
[{'alpha': [0.1, 0.25, 0.5, 0.75, 1.0]}]
```

RandomForestClassifier and RandomForestRegressor

```
[{'max_depth': [1, 5, 10, None]}]
```

Ridge and RidgeClassifier

```
[{'alpha': [0.01, 0.1, 1.0, 10.0, 100.0]}]
```

SGDClassifier and SGDRegressor

```
[{'alpha': [0.000001, 0.00001, 0.0001, 0.001, 0.01],
  'penalty': ['l1', 'l2', 'elasticnet']}
```

SVC

```
[{'C': [0.01, 0.1, 1.0, 10.0, 100.0],
  'gamma': ['auto', 0.01, 0.1, 1.0, 10.0, 100.0]}]
```

SVR

```
[{'C': [0.01, 0.1, 1.0, 10.0, 100.0]}]
```

Note: Note that learners not listed here do not have any default parameter grids in SKLL either because there are no hyper-parameters to tune or decisions about which parameters to tune (and how) depend on the data being used for the experiment and are best left up to the user.

**pos_label_str (Optional)**

A string denoting the label of the class to be treated as the positive class in a binary classification setting. If unspecified, the class represented by the label that appears second when sorted is chosen as the positive class. For example, if the two labels in data are “A” and “B” and pos_label_str is not specified, “B” will be chosen as the positive class.
use_folds_file_for_grid_search (*Optional*)

Whether to use the specified folds_file for the inner grid-search cross-validation loop when task is set to cross_validate. Defaults to True.

**Note:** This flag is ignored for all other tasks, including the train task where a specified folds_file is always used for the grid search.

**Output**

The fields in this section generally pertain to the output files produced by the experiment. The most common fields are logs, models, predictions, and results. These fields are mostly optional although they may be required in certain cases. A common option is to use the same directory for all of these fields.

**log (*Optional*)**

Directory to store SKLL log files in. If omitted, the current working directory is used.

**models (*Optional*)**

Directory in which to store trained models. Can be omitted to not store models except when using the train task, where this path must be specified. On the other hand, this path must not be specified for the learning_curve task.

**metrics (*Optional*)**

For the evaluate and cross_validate tasks, this is an optional list of additional metrics that will be computed in addition to the tuning objectives and added to the results files. However, for the learning_curve task, this list is required. Possible values are all of the same functions as those available for the tuning objectives (with the same caveats).

**Note:** If the list of metrics overlaps with the grid search tuning objectives, then, for each job, the objective that overlaps is not computed again as a metric. Recall that each SKLL job can only contain a single tuning objective. Therefore, if, say, the objectives list is ['accuracy', 'roc_auc'] and the metrics list is ['roc_auc', 'average_precision'], then in the second job, roc_auc is used as the objective but not computed as an additional metric.
pipeline *(Optional)*

Whether or not the final learner object should contain a `pipeline` attribute that contains a scikit-learn `Pipeline` object composed of copies of each of the following steps of training the learner:

- feature vectorization (*vectorizer*)
- feature selection (*selector*)
- feature sampling (*sampler*)
- feature scaling (*scaler*)
- main estimator (*estimator*)

The strings in the parentheses represent the name given to each step in the pipeline.

The goal of this attribute is to allow better interoperability between SKLL learner objects and scikit-learn. The user can train the model in SKLL and then further tweak or analyze the pipeline in scikit-learn, if needed. Each component of the pipeline is a (deep) copy of the component that was fit as part of the SKLL model training process. We use copies since we do not want the original SKLL model to be affected if the user modifies the components of the pipeline in scikit-learn space.

Here’s an example of how to use this attribute.

```python
from sklearn.preprocessing import LabelEncoder
from skll import Learner
from skll.data import Reader

# train a classifier and a regressor using the SKLL API
fs1 = Reader.for_path('examples/iris/train/example_iris_features.jsonlines').read()
learner1 = Learner('LogisticRegression', pipeline=True)
_ = learner1.train(fs1, grid_search=True, grid_objective='f1_score_macro')

fs2 = Reader.for_path('examples/boston/train/example_boston_features.jsonlines').read()
learner2 = Learner('RescaledSVR', feature_scaling='both', pipeline=True)
_ = learner2.train(fs2, grid_search=True, grid_objective='pearson')

# now, we can explore the stored pipelines in sklearn space
enc = LabelEncoder().fit(fs1.labels)

# first, the classifier
D1 = {"f0": 6.1, "f1": 2.8, "f2": 4.7, "f3": 1.2}
pipeline1 = learner1.pipeline
```

(continues on next page)
enc.inverse_transform(pipeline1.predict(D1))

# then, the regressor
D2 = {"f0": 0.09178, "f1": 0.0, "f2": 4.05, "f3": 0.0, "f4": 0.51, "f5": 6.416, "f6": 84.1, "f7": 2.6463, "f8": 5.0, "f9": 296.0, "f10": 16.6, "f11": 395.5, "f12": 9.04}

pipeline2 = learner2.pipeline
pipeline2.predict(D2)

# note that without the `pipeline` attribute, one would have to do the following for D1, which is much less readable

enc.inverse_transform(learner1.model.predict(learner1.scaler.transform(learner1.feat_selector.transform(learner1.feat_vectorizer.transform(D1)))))

---

**Note:**

1. When using a DictVectorizer in SKLL along with feature scaling set to either with_mean or both, the sparse attribute of the vectorizer stage in the pipeline is set to False since centering requires dense arrays.

2. When feature hashing is used (via a FeatureHasher) in SKLL along with feature scaling set to either with_mean or both, a custom pipeline stage (skll.learner.Densifier) is inserted in the pipeline between the feature vectorization (here, hashing) stage and the feature scaling stage. This is necessary since a FeatureHasher does not have a sparse attribute to turn off – it only returns sparse vectors.

3. A Densifier is also inserted in the pipeline when using a SkewedChi2Sampler for feature sampling since this sampler requires dense input and cannot be made to work with sparse arrays.

---

**predictions (Optional)**

Directory in which to store prediction files. Can be omitted to not store predictions. Must not be specified for the learning_curve and train tasks.

**probability (Optional)**

Whether or not to output probabilities for each class instead of the most probable class for each instance. Only really makes a difference when storing predictions. Defaults to False. Note that this also applies to the tuning objective.
results (Optional)

Directory in which to store result files. If omitted, the current working directory is used.

save_cv_folds (Optional)

Whether to save the folds file containing the folds for a cross-validation experiment. Defaults to False.

save_cv_models (Optional)

Whether to save each of the K model files trained during each step of a K-fold cross-validation experiment. Defaults to False.

1.4.4 Using run_experiment

Once you have created the configuration file for your experiment, you can usually just get your experiment started by running run_experiment CONFIGFILE. That said, there are a few options that are specified via command-line arguments instead of in the configuration file:

-a <num_features>, --ablation <num_features>

Runs an ablation study where repeated experiments are conducted with the specified number of feature files in each featureset in the configuration file held out. For example, if you have three feature files (A, B, and C) in your featureset and you specify --ablation 1, there will be three experiments conducted with the following featuresets: [[A, B], [B, C], [A, C]]. Additionally, since every ablation experiment includes a run with all the features as a baseline, the following featureset will also be run: [[A, B, C]].

If you would like to try all possible combinations of feature files, you can use the run_experiment --ablation_all option instead.

| Warning: | Ablation will not work if you specify a train_file and test_file since no featuresets are defined in that scenario. |

-A, --ablation_all

Runs an ablation study where repeated experiments are conducted with all combinations of feature files in each featureset.

---

3 If you installed SKLL via pip on macOS, you might get an error when using run_experiment to generate learning curves. To get around this, add MPLBACKEND=Agg before the run_experiment command and re-run.
Warning: This can create a huge number of jobs, so please use with caution.

-k, --keep-models
If trained models already exist for any of the learner/featureset combinations in your configuration file, just load those models and do not retrain/overwrite them.

-r, --resume
If result files already exist for an experiment, do not overwrite them. This is very useful when doing a large ablation experiment and part of it crashes.

-v, --verbose
Print more status information. For every additional time this flag is specified, output gets more verbose.

--version
Show program’s version number and exit.

GridMap options
If you have GridMap installed, run_experiment will automatically schedule jobs on your DRMAA-compatible cluster. You can use the following options to customize this behavior.

-l, --local
Run jobs locally instead of using the cluster.\footnote{This will happen automatically if GridMap cannot be imported.}

-q <queue>, --queue <queue>
Use this queue for GridMap. (default: all.q)

-m <machines>, --machines <machines>
Comma-separated list of machines to add to GridMap’s whitelist. If not specified, all available machines are used.

Note: Full names must be specified, (e.g., nlp.research.ets.org).

1.4.5 Output files

For most of the SKLL tasks the various output files generated by run_experiment share the automatically generated prefix <EXPERIMENT>_<FEATURESET>_<LEARNER>_<OBJECTIVE>, where the following definitions hold:

<EXPERIMENT> The value of the experiment_name field in the configuration file.

<FEATURESET> The components of the feature set that was used for training, joined with “+”.

1.4. Running Experiments
<LEARNER>  The learner that was used to generate the current results/model/etc.

<OBJECTIVE>  The objective function that was used to generate the current results/model/etc.

Note: In SKLL terminology, a specific combination of featuresets, learners, and objectives specified in the configuration file is called a job. Therefore, an experiment (represented by a configuration file) can contain multiple jobs.

However, if the objectives field in the configuration file contains only a single value, the job can be disambiguated using only the featuresets and the learners since the objective is fixed. Therefore, the output files will have the prefix <EXPERIMENT>_<FEATURESET>_<LEARNER>.

The following types of output files can be generated after running an experiment configuration file through run_experiment. Note that some file types may or may not be generated depending on the values of the fields specified in the Output section of the configuration file.

**Log files**

SKLL produces two types of log files – one for each job in the experiment and a single, top level log file for the entire experiment. Each of the job log files have the usual job prefix as described above whereas the experiment log file is simply named <EXPERIMENT>.log.

While the job-level log files contain messages that pertain to the specific characteristics of the job (e.g., warnings from scikit-learn pertaining to the specific learner), the experiment-level log file will contain logging messages that pertain to the overall experiment and configuration file (e.g., an incorrect option specified in the configuration file). The messages in all SKLL log files are in the following format:

<TIMESTAMP> - <LEVEL> - <MSG>

where <TIMESTAMP> refers to the exact time when the message was logged, <LEVEL> refers to the level of the logging message (e.g., INFO, WARNING, etc.), and <MSG> is the actual content of the message. All of the messages are also printed to the console in addition to being saved in the job-level log files and the experiment-level log file.

**Model files**

Model files end in .model and are serialized skll.learner.Learner instances. run_experiment will re-use existing model files if they exist, unless it is explicitly told not to. These model files can also be loaded programmatically via the SKLL API, specifically the skll.learner.Learner.from_file() method.
Results files

SKLL generates two types of result files:

1. Files ending in `.results` which contain a human-readable summary of the job, complete with confusion matrix, objective function score on the test set, and values of any additional metrics specified via the `metrics` configuration file option.

2. Files ending in `.results.json`, which contain all of the same information as the `.results` files, but in a format more well-suited to automated processing. In some cases, `.results.json` files may contain more information than their `.results` file counterparts. For example, when doing grid search for tuning model hyperparameters, these files contain an additional attribute `grid_search_cv_results` containing detailed results from the grid search process.

Prediction files

Predictions files are TSV files that contain either the predicted values (for regression) OR predicted labels/class probabilities (for classification) for each instance in the test feature set. The value of the `probability` option decides whether SKLL outputs the labels or the probabilities.

When the predictions are labels or values, there are only two columns in the file: one containing the ID for the instance and the other containing the prediction. The headers for the two columns in this case are “id” and “prediction”.

When the predictions are class probabilities, there are $N+1$ columns in these files, where $N$ is the number of classes in the training data. The header for the column containing IDs is still “id” and the labels themselves are the headers for the columns containing their respective probabilities. In the special case of binary classification, the positive class probabilities are always in the last column.

Summary file

For every experiment you run, there will also be an experiment summary file generated that is a tab-delimited file summarizing the results for each job in the experiment. It is named `<EXPERIMENT>_summary.tsv`. For learning_curve experiments, this summary file will contain training set sizes and the averaged scores for all combinations of featuresets, learners, and objectives.

Folds file

For the cross_validate task, SKLL can also output the actual folds and instance IDs used in the cross-validation process, if the `save_cv_folds` option is enabled. In this case, a file called `<EXPERIMENT>_skll_fold_ids.csv` is saved to disk.
Learning curve plots

When running a `learning_curve` experiment, actual learning curves are also generated as PNG files - one for each feature set specified in the configuration file. Each PNG file is named `EXPERIMENT_FEATURESET.png` and contains a faceted learning curve plot for the feature-set with objective functions on rows and learners on columns. Here’s an example of such a plot.

You can also generate the plots from the learning curve summary file using the `plot_learning_curves` utility script.

1.5 Utility Scripts

In addition to the main script, `run_experiment`, SKLL comes with a number of helpful utility scripts that can be used to prepare feature files and perform other routine tasks. Each is described briefly below.

1.5.1 `compute_eval_from_predictions`

Compute evaluation metrics from prediction files after you have run an experiment.

Positional Arguments

`examples_file`
  SKLL input file with labeled examples

`predictions_file`
  file with predictions from SKLL
metric_names
metrics to compute

Optional Arguments

--version
Show program’s version number and exit.

1.5.2 filter_features

Filter feature file to remove (or keep) any instances with the specified IDs or labels. Can also be used to remove/keep feature columns.

Positional Arguments

infile
Input feature file (ends in .arff, .csv, .jsonlines, .megam, .ndj, or .tsv)

outfile
Output feature file (must have same extension as input file)

Optional Arguments

-f <feature <feature ...>>, --feature <feature <feature ...>>
A feature in the feature file you would like to keep. If unspecified, no features are removed.

-I <id <id ...>>, --id <id <id ...>>
An instance ID in the feature file you would like to keep. If unspecified, no instances are removed based on their IDs.

-i, --inverse
Instead of keeping features and/or examples in lists, remove them.

--id_col <id_col>
Name of the column which contains the instance IDs in ARFF, CSV, or TSV files. (default: id)

-L <label <label ...>>, --label <label <label ...>>
A label in the feature file you would like to keep. If unspecified, no instances are removed based on their labels.

-l <label_col>, --label_col <label_col>
Name of the column which contains the class labels in ARFF, CSV, or TSV files. For ARFF files, this must be the final column to count as the label. (default: y)
-db, --drop-blanks
  Drop all lines/rows that have any blank values. (default: False)

-rb <replacement>, --replace-blanks-with <replacement>
  Specifies a new value with which to replace blank values in all columns in the file. To replace blanks differently in each column, use the SKLL Reader API directly. (default: None)

-q, --quiet
  Suppress printing of "Loading..." messages.

--version
  Show program’s version number and exit.

1.5.3 generate_predictions

Loads a trained model and outputs predictions based on input feature files. Useful if you want to reuse a trained model as part of a larger system without creating configuration files. Offers the following modes of operation:

- For non-probabilistic classification and regression, generate the predictions.
- For probabilistic classification, generate either the most likely labels or the probabilities for each class label.
- For binary probabilistic classification, generate the positive class label only if its probability exceeds the given threshold. The positive class label is either read from the model file or inferred the same way as a SKLL learner would.

Positional Arguments

model_file
  Model file to load and use for generating predictions.

input_file(s)
  One or more csv file(s), jsonlines file(s), or megam file(s) (with or without the label column), with the appropriate suffix.

Optional Arguments

-i <id_col>, --id_col <id_col>
  Name of the column which contains the instance IDs in ARFF, CSV, or TSV files. (default: id)
-l <label_col>, --label_col <label_col>
   Name of the column which contains the labels in ARFF, CSV, or TSV files. For ARFF files, this must be the final column to count as the label. (default: y)

-o <path>, --output_file <path>
   Path to output TSV file. If not specified, predictions will be printed to stdout. For probabilistic binary classification, the probability of the positive class will always be in the last column.

-p, --predict_labels
   If the model does probabilistic classification, output the class label with the highest probability instead of the class probabilities.

-q, --quiet
   Suppress printing of "Loading..." messages.

-t <threshold>, --threshold <threshold>
   If the model does binary probabilistic classification, return the positive class label only if it meets/exceeds the given threshold and the other class label otherwise.

--version
   Show program’s version number and exit.

1.5.4 join_features

Combine multiple feature files into one larger file.

Positional Arguments

infile ...
   Input feature files (ends in .arff, .csv, .jsonlines, .megam, .ndj, or .tsv)

outfile
   Output feature file (must have same extension as input file)

Optional Arguments

-1 <label_col>, --label_col <label_col>
   Name of the column which contains the labels in ARFF, CSV, or TSV files. For ARFF files, this must be the final column to count as the label. (default: y)

-q, --quiet
   Suppress printing of "Loading..." messages.
1.5.5 plot_learning_curves

Generate learning curve plots from a learning curve output TSV file.

**Positional Arguments**

- **tsv_file**
  Input learning Curve TSV output file.

- **output_dir**
  Output directory to store the learning curve plots.

1.5.6 print_model_weights

Prints out the weights of a given trained model. If the model was trained using feature hashing, feature names of the form `hashed_feature_XX` will be used since the original feature names no longer apply.

**Positional Arguments**

- **model_file**
  Model file to load.

**Optional Arguments**

- **--k <k>**
  Number of top features to print (0 for all) (default: 50)

- **--sign {positive, negative, all}**
  Show only positive, only negative, or all weights (default: all)

- **--sort_by_labels**
  Order the features by classes (default: False). Mutually exclusive with the --k option.

- **--version**
  Show program’s version number and exit.
1.5.7 skll_convert

Convert between .arff, .csv, .jsonlines, .libsvm, .megam, and .tsv formats.

Positional Arguments

infile
Input feature file (ends in .arff, .csv, .jsonlines, .libsvm, .megam, .ndj, or .tsv)

outfile
Output feature file (ends in .arff, .csv, .jsonlines, .libsvm, .megam, .ndj, or .tsv)

Optional Arguments

-l <label_col>, --label_col <label_col>
Name of the column which contains the labels in ARFF, CSV, or TSV files. For ARFF files, this must be the final column to count as the label. (default: y)

-q, --quiet
Suppress printing of "Loading..." messages.

--arff_regression
Create ARFF files for regression, not classification.

--arff_relation ARFF_RELATION
Relation name to use for ARFF file. (default: skll_relation)

--no_labels
Used to indicate that the input data has no labels.

--reuse_libsvm_map REUSE_LIBSVM_MAP
If you want to output multiple files that use the same mapping from labels and features to numbers when writing libsvm files, you can specify an existing .libsvm file to reuse the mapping from.

--version
Show program’s version number and exit.

1.5.8 summarize_results

Creates an experiment summary TSV file from a list of JSON files generated by run_experiment.
Positional Arguments

**summary_file**
- TSV file to store summary of results.

**json_file**
- JSON results file generated by run_experiment.

Optional Arguments

- `-a, --ablation`
  - The results files are from an ablation run.

- `--version`
  - Show program’s version number and exit.

# 1.6 API Documentation

## 1.6.1 Quickstart

Here is a quick run-down of how you accomplish common tasks.

Load a FeatureSet from a file:

```python
from skll import Reader

example_reader = Reader.for_path('myexamples.megam')
train_examples = example_reader.read()
```

Or, work with an existing pandas DataFrame:

```python
from skll import FeatureSet

train_examples = FeatureSet.from_data_frame(my_data_frame, 'A Name for My Data', labels_column='name of the column containing the data labels')
```

Train a linear svm (assuming we have `train_examples`):

```python
from skll import Learner

learner = Learner('LinearSVC')
learner.train(train_examples)
```

Evaluate a trained model:
test_examples = Reader.for_path('test.tsv').read()
conf_matrix, accuracy, prf_dict, model_params, obj_score = learner.
→evaluate(test_examples)

Perform ten-fold cross-validation with a radial SVM:

learner = Learner('SVC')
fold_result_list, grid_search_scores = learner.cross-validate(train_
→examples)

fold_result_list in this case is a list of the results returned by learner.evaluate for
each fold, and grid_search_scores is the highest objective function value achieved when
tuning the model.

Generate predictions from a trained model:

predictions = learner.predict(test_examples)

1.6.2 skll Package

The most useful parts of our API are available at the package level in addition to the module level.
They are documented in both places for convenience.

From data Package

class skll.FeatureSet(name, ids, labels=None, features=None, vector-
izer=None)

Bases: object

Encapsulation of all of the features, values, and metadata about a given set of data. This
replaces ExamplesTuple from older versions of SKLL.

Parameters

- **name** *(str)* – The name of this feature set.
- **ids** *(np.array)* – Example IDs for this set.
- **labels** *(np.array, optional)* – labels for this set. Defaults to None.
- **feature** *(list of dict or array-like, optional)* – The features for each instance represented as either a list of dictionaries
  or an array-like (if vectorizer is also specified). Defaults to None.
• **vectorizer** *(DictVectorizer or FeatureHasher, optional)* – Vectorizer which will be used to generate the feature matrix. Defaults to None.

**Warning:** FeatureSets can only be equal if the order of the instances is identical because these are stored as lists/arrays. Since scikit-learn’s DictVectorizer automatically sorts the underlying feature matrix if it is sparse, we do not do any sorting before checking for equality. This is not a problem because we _always_ use sparse matrices with DictVectorizer when creating FeatureSets.

**Notes**

If ids, labels, and/or features are not None, the number of rows in each array must be equal.

**filter (ids=None, labels=None, features=None, inverse=False)**

Removes or keeps features and/or examples from the Featureset depending on the parameters. Filtering is done in-place.

**Parameters**

- **ids** *(list of str/float, optional)* – Examples to keep in the FeatureSet. If None, no ID filtering takes place. Defaults to None.

- **labels** *(list of str/float, optional)* – Labels that we want to retain examples for. If None, no label filtering takes place. Defaults to None.

- **features** *(list of str, optional)* – Features to keep in the FeatureSet. To help with filtering string-valued features that were converted to sequences of boolean features when read in, any features in the FeatureSet that contain a = will be split on the first occurrence and the prefix will be checked to see if it is in features. If None, no feature filtering takes place. Cannot be used if FeatureSet uses a FeatureHasher for vectorization. Defaults to None.

- **inverse** *(bool, optional)* – Instead of keeping features and/or examples in lists, remove them. Defaults to False.

**Raises** ValueError – If attempting to use features to filter a FeatureSet that uses a FeatureHasher vectorizer.

**filtered_iter (ids=None, labels=None, features=None, inverse=False)**

A version of __iter__ that retains only the specified features and/or examples from the output.

**Parameters**
• **ids** (*list of str/float, optional*) – Examples to keep in the `FeatureSet`. If None, no ID filtering takes place. Defaults to None.

• **labels** (*list of str/float, optional*) – Labels that we want to retain examples for. If None, no label filtering takes place. Defaults to None.

• **features** (*list of str, optional*) – Features to keep in the `FeatureSet`. To help with filtering string-valued features that were converted to sequences of boolean features when read in, any features in the `FeatureSet` that contain a `=` will be split on the first occurrence and the prefix will be checked to see if it is in `features`. If None, no feature filtering takes place. Cannot be used if `FeatureSet` uses a `FeatureHasher` for vectorization. Defaults to None.

• **inverse** (*bool, optional*) – Instead of keeping features and/or examples in lists, remove them. Defaults to False.

**Yields**

• **id_** (*str*) – The ID of the example.

• **label_** (*str*) – The label of the example.

• **feat_dict** (*dict*) – The feature dictionary, with feature name as the key and example value as the value.

**Raises** *ValueError* – If the vectorizer is not a `DictVectorizer`.

#### `static from_data_frame(df, name, labels_column=None, vectorizer=None)`

Helper function to create a `FeatureSet` instance from a `pandas.DataFrame`. Will raise an Exception if pandas is not installed in your environment. The ids in the `FeatureSet` will be the index from the given frame.

**Parameters**

• **df** (*pd.DataFrame*) – The pandas.DataFrame object to use as a `FeatureSet`.

• **name** (*str*) – The name of the output `FeatureSet` instance.

• **labels_column** (*str, optional*) – The name of the column containing the labels (data to predict). Defaults to None.

• **vectorizer** (*`DictVectorizer` or `FeatureHasher`, optional*) – Vectorizer which will be used to generate the feature matrix. Defaults to None.

**Returns** `feature_set` – A `FeatureSet` instance generated from from the given data frame.

**Return type** *skll.FeatureSet*
**has_labels**
Check if FeatureSet has finite labels.

**Returns** has_labels – Whether or not this FeatureSet has any finite labels.

**Return type** bool

**static split_by_ids** (fs, ids_for_split1, ids_for_split2=None)
Split the FeatureSet into two new FeatureSet instances based on the given IDs for the two splits.

**Parameters**

- **fs** (skll.FeatureSet) – The FeatureSet instance to split.
- **ids_for_split1** (list of int) – A list of example IDs which will be split out into the first FeatureSet instance. Note that the FeatureSet instance will respect the order of the specified IDs.
- **ids_for_split2** (list of int, optional) – An optional list of example IDs which will be split out into the second FeatureSet instance. Note that the FeatureSet instance will respect the order of the specified IDs. If this is not specified, then the second FeatureSet instance will contain the complement of the first set of IDs sorted in ascending order. Defaults to None.

**Returns**

- **fs1** (skll.FeatureSet) – The first FeatureSet.
- **fs2** (skll.FeatureSet) – The second FeatureSet.

**class skll.Reader** (path_or_list, quiet=True, ids_to_floats=False, label_col='y', id_col='id', class_map=None, sparse=True, feature_hasher=False, num_features=None, logger=None)

Bases: object

A helper class to make picklable iterators out of example dictionary generators.

**Parameters**

- **path_or_list** (str or list of dict) – Path or a list of example dictionaries.
- **quiet** (bool, optional) – Do not print “Loading…” status message to stderr. Defaults to True.
- **ids_to_floats** (bool, optional) – Convert IDs to float to save memory. Will raise error if we encounter an a non-numeric ID. Defaults to False.
- **label_col** (str, optional) – Name of the column which contains the class labels for ARFF/CSV/TSV files. If no column with that
name exists, or None is specified, the data is considered to be unlabelled. Defaults to 'y'.

- **id_col**(str, optional) – Name of the column which contains the instance IDs. If no column with that name exists, or None is specified, example IDs will be automatically generated. Defaults to 'id'.

- **class_map**(dict, optional) – Mapping from original class labels to new ones. This is mainly used for collapsing multiple labels into a single class. Anything not in the mapping will be kept the same. Defaults to None.

- **sparse**(bool, optional) – Whether or not to store the features in a numpy CSR matrix when using a DictVectorizer to vectorize the features. Defaults to True.

- **feature_hasher**(bool, optional) – Whether or not a FeatureHasher should be used to vectorize the features. Defaults to False.

- **num_features**(int, optional) – If using a FeatureHasher, how many features should the resulting matrix have? You should set this to a power of 2 greater than the actual number of features to avoid collisions. Defaults to None.

- **logger**(logging.Logger, optional) – A logger instance to use to log messages instead of creating a new one by default. Defaults to None.

classmethod **for_path**(path_or_list, **kwargs)

Instantiate the appropriate Reader sub-class based on the file extension of the given path. Or use a dictionary reader if the input is a list of dictionaries.

Parameters

- **path_or_list**(str or list of dicts) – A path or list of example dictionaries.

- **kwargs**(dict, optional) – The arguments to the Reader object being instantiated.

Returns reader – A new instance of the Reader sub-class that is appropriate for the given path.

Return type *skll.Reader*

Raises ValueError – If file does not have a valid extension.

**read**()

Loads examples in the .arff, .csv, .jsonlines, .libsvm, .megam, .ndj, or .tsv formats.

Returns feature_set – FeatureSet instance representing the input file.

Return type *skll.FeatureSet*
Raises

- `ValueError` – If `ids_to_floats` is True, but IDs cannot be converted.
- `ValueError` – If no features are found.
- `ValueError` – If the example IDs are not unique.

```python
class skll.Writer(path, feature_set, **kwargs)
    Bases: object

    Helper class for writing out FeatureSets to files on disk.

    Parameters

    - `path`(str) – A path to the feature file we would like to create. The suffix to this filename must be `.arff`, `.csv`, `.jsonlines`, `.libsvm`, `.megam`, `.ndj`, or `.tsv`. If `subsets` is not None, when calling the `write()` method, path is assumed to be a string containing the path to the directory to write the feature files with an additional file extension specifying the file type. For example `/foo/.csv`.
    - `feature_set`(skll.FeatureSet) – The FeatureSet instance to dump to the file.
    - `quiet`(bool) – Do not print “Writing...” status message to stderr. Defaults to True.
    - `subsets`(dict (str to list of str)) – A mapping from subset names to lists of feature names that are included in those sets. If given, a feature file will be written for every subset (with the name containing the subset name as suffix to `path`). Note, since string-valued features are automatically converted into boolean features with names of the form `FEATURE_NAME=STRING_VALUE`, when doing the filtering, the portion before the `=` is all that’s used for matching. Therefore, you do not need to enumerate all of these boolean feature names in your mapping. Defaults to None.
    - `logger`(logging.Logger) – A logger instance to use to log messages instead of creating a new one by default. Defaults to None.

classmethod for_path(path, feature_set, **kwargs)
    Retrieve object of `Writer` sub-class that is appropriate for given path.

    Parameters

    - `path`(str) – A path to the feature file we would like to create. The suffix to this filename must be `.arff`, `.csv`, `.jsonlines`, `.libsvm`, `.megam`, `.ndj`, or `.tsv`. If `subsets` is not None, when calling the `write()` method, path is assumed to be a string containing
the path to the directory to write the feature files with an additional file extension specifying the file type. For example /foo/.csv.

- **feature_set** (skll.FeatureSet) – The FeatureSet instance to dump to the output file.

- **kwargs** (dict) – The keyword arguments for for_path are the same as the initializer for the desired Writer subclass.

**Returns** writer – New instance of the Writer sub-class that is appropriate for the given path.

**Return type** skll.data.writers.Writer

write()  
Writes out this Writer’s FeatureSet to a file in its format.

**From experiments Module**

skll.run_configuration(config_file, local=False, overwrite=True, queue='all.q',  
hosts=None, write_summary=True, quiet=False, ablation=0, resume=False, log_level=20)

Takes a configuration file and runs the specified jobs on the grid.

**Parameters**

- **config_file** (str) – Path to the configuration file we would like to use.

- **local** (bool, optional) – Should this be run locally instead of on the cluster? Defaults to False.

- **overwrite** (bool, optional) – If the model files already exist, should we overwrite them instead of re-using them? Defaults to True.

- **queue** (str, optional) – The DRMAA queue to use if we’re running on the cluster. Defaults to 'all.q'.

- **hosts** (list of str, optional) – If running on the cluster, these are the machines we should use. Defaults to None.

- **write_summary** (bool, optional) – Write a TSV file with a summary of the results. Defaults to True.

- **quiet** (bool, optional) – Suppress printing of “Loading...” messages. Defaults to False.

- **ablation** (int, optional) – Number of features to remove when doing an ablation experiment. If positive, we will perform repeated ablation runs for all combinations of features removing the specified number at a time. If None, we will use all combinations of all lengths. If 0, the
default, no ablation is performed. If negative, a `ValueError` is raised. Defaults to 0.

- **resume** (`bool, optional`) – If result files already exist for an experiment, do not overwrite them. This is very useful when doing a large ablation experiment and part of it crashes. Defaults to `False`.

- **log_level** (`str, optional`) – The level for logging messages. Defaults to `logging.INFO`.

**Returns** `result_json_paths` – A list of paths to .json results files for each variation in the experiment.

**Return type** list of str

**Raises**

- `ValueError` – If value for "ablation" is not a positive int or None.
- `OSError` – If the length of the FeatureSet name > 210.

---

**From learner Module**

```python
class skll.Learner(model_type='LogisticRegression', probability=False, pipeline=False, feature_scaling='none', model_kwargs=None, pos_label_str=None, min_feature_count=1, sampler=None, sampler_kwargs=None, custom_learner_path=None, logger=None)
```

**Bases:** `object`

A simpler learner interface around many scikit-learn classification and regression functions.

**Parameters**

- **model_type** (`str`) – Name of estimator to create (e.g., 'LogisticRegression'). See the skll package documentation for valid options.

- **probability** (`bool, optional`) – Should learner return probabilities of all labels (instead of just label with highest probability)? Defaults to False.

- **pipeline** (`bool, optional`) – Should learner contain a pipeline attribute that contains a scikit-learn Pipeline object composed of all steps including the vectorizer, the feature selector, the sampler, the feature scaler, and the actual estimator. Note that this will increase the size of the learner object in memory and also when it is saved to disk. Defaults to False.
• **feature_scaling** *(str, optional)* – How to scale the features, if at all. Options are - 'with_std': scale features using the standard deviation - 'with_mean': center features using the mean - 'both': do both scaling as well as centering - 'none': do neither scaling nor centering. Defaults to 'none'.

• **model_kwargs** *(dict, optional)* – A dictionary of keyword arguments to pass to the initializer for the specified model. Defaults to None.

• **pos_label_str** *(str, optional)* – A string denoting the label of the class to be treated as the positive class in a binary classification setting. If None, the class represented by the label that appears second when sorted is chosen as the positive class. For example, if the two labels in data are “A” and “B” and pos_label_str is not specified, “B” will be chosen as the positive class. Defaults to None.

• **min_feature_count** *(int, optional)* – The minimum number of examples a feature must have a nonzero value in to be included. Defaults to 1.

• **sampler** *(str, optional)* – The sampler to use for kernel approximation, if desired. Valid values are - ‘AdditiveChi2Sampler’ - ‘Nystroem’ - ‘RBFSampler’ - ‘SkewedChi2Sampler’ Defaults to None.

• **sampler_kwargs** *(dict, optional)* – A dictionary of keyword arguments to pass to the initializer for the specified sampler. Defaults to None.

• **custom_learner_path** *(str, optional)* – Path to module where a custom classifier is defined. Defaults to None.

• **logger** *(logging object, optional)* – A logging object. If None is passed, get logger from **__name__**. Defaults to None.

```python
cross_validate(examples, stratified=True, cv_folds=10, grid_search=True, grid_search_folds=3, grid_jobs=None, grid_objective=None, output_metrics=[], prediction_prefix=None, param_grid=None, shuffle=False, save_cv_folds=False, save_cv_models=False, use_custom_folds_for_grid_search=True)
```

Cross-validates a given model on the training examples.

**Parameters**

• **examples** *(skll.FeatureSet)* – The FeatureSet instance to cross-validate learner performance on.

• **stratified** *(bool, optional)* – Should we stratify the folds to ensure an even distribution of labels for each fold? Defaults to True.
• **cv_folds** *(int, optional)* – The number of folds to use for cross-validation, or a mapping from example IDs to folds. Defaults to 10.

• **grid_search** *(bool, optional)* – Should we do grid search when training each fold? Note: This will make this take much longer. Defaults to False.

• **grid_search_folds** *(int or dict, optional)* – The number of folds to use when doing the grid search, or a mapping from example IDs to folds. Defaults to 3.

• **grid_jobs** *(int, optional)* – The number of jobs to run in parallel when doing the grid search. If None or 0, the number of grid search folds will be used. Defaults to None.

• **grid_objective** *(str, optional)* – The name of the objective function to use when doing the grid search. Must be specified if grid_search is True. Defaults to None.

• **output_metrics** *(list of str, optional)* – List of additional metric names to compute in addition to the metric used for grid search. Empty by default. Defaults to an empty list.

• **prediction_prefix** *(str, optional)* – If saving the predictions, this is the prefix that will be used for the filename. It will be followed by "_predictions.tsv" Defaults to None.

• **param_grid** *(list of dicts, optional)* – The parameter grid to traverse. Defaults to None.

• **shuffle** *(bool, optional)* – Shuffle examples before splitting into folds for CV. Defaults to False.

• **save_cv_folds** *(bool, optional)* – Whether to save the cv fold ids or not? Defaults to False.

• **save_cv_models** *(bool, optional)* – Whether to save the cv models or not? Defaults to False.

• **use_custom_folds_for_grid_search** *(bool, optional)* – If cv_folds is a custom dictionary, but grid_search_folds is not, perhaps due to user oversight, should the same custom dictionary automatically be used for the inner grid-search cross-validation? Defaults to True.

### Returns

• **results** *(list of 6-tuples)* – The confusion matrix, overall accuracy, per-label PRFs, model parameters, objective function score, and evaluation metrics (if any) for each fold.
• **grid_search_scores** *(list of floats)* – The grid search scores for each fold.

• **grid_search_cv_results_dicts** *(list of dicts)* – A list of dictionaries of grid search CV results, one per fold, with keys such as “params”, “mean_test_score”, etc, that are mapped to lists of values associated with each hyperparameter set combination.

• **skll_fold_ids** *(dict)* – A dictionary containing the test-fold number for each id if `save_cv_folds` is True, otherwise None.

• **models** *(list of skll.learner.Learner)* – A list of skll.learner.Learners, one for each fold if `save_cv_models` is True, otherwise None.

**Raises** `ValueError` – If labels are not encoded as strings.

**evaluate**(examples, prediction_prefix=None, append=False, grid_objective=None, output_metrics=[]) Evaluates a given model on a given dev or test FeatureSet.

**Parameters**

• **examples** *(skll.FeatureSet)* – The FeatureSet instance to evaluate the performance of the model on.

• **prediction_prefix** *(str, optional)* – If saving the predictions, this is the prefix that will be used for the filename. It will be followed by "_predictions.tsv". Defaults to None.

• **append** *(bool, optional)* – Should we append the current predictions to the file if it exists? Defaults to False.

• **grid_objective** *(function, optional)* – The objective function that was used when doing the grid search. Defaults to None.

• **output_metrics** *(list of str, optional)* – List of additional metric names to compute in addition to grid objective. Empty by default. Defaults to an empty list.

**Returns** *res* – The confusion matrix, the overall accuracy, the per-label PRFs, the model parameters, the grid search objective function score, and the additional evaluation metrics, if any.

**Return type** 6-tuple

**classmethod from_file**(learner_path, logger=None) Load a saved Learner instance from a file path.

**Parameters**

• **learner_path** *(str)* – The path to a saved Learner instance file.
• **logger** (*logging object, optional*) – A logging object. If `None` is passed, get logger from `__name__`. Defaults to `None`.

**Returns** `learner` – The `Learner` instance loaded from the file.

**Return type** `skll.Learner`

**Raises**

- `ValueError` – If the pickled object is not a `Learner` instance.
- `ValueError` – If the pickled version of the `Learner` instance is out of date.

**learning_curve** (*examples, metric, cv_folds=10, train_sizes=\([0.1, 0.325, 0.55, 0.775, 1.0]\]*)

Generates learning curves for a given model on the training examples via cross-validation. Adapted from the scikit-learn code for learning curve generation (cf. `'sklearn.model_selection.learning_curve'`).

**Parameters**

- **examples** (*skll.FeatureSet*) – The `FeatureSet` instance to generate the learning curve on.
- **cv_folds** (*int, optional*) – The number of folds to use for cross-validation, or a mapping from example IDs to folds. Defaults to 10.
- **metric** (*str*) – The name of the metric function to use when computing the train and test scores for the learning curve.
- **train_sizes** (*list of float or int, optional*) – Relative or absolute numbers of training examples that will be used to generate the learning curve. If the type is float, it is regarded as a fraction of the maximum size of the training set (that is determined by the selected validation method), i.e. it has to be within (0, 1]. Otherwise it is interpreted as absolute sizes of the training sets. Note that for classification the number of samples usually have to be big enough to contain at least one sample from each class. Defaults to `np.linspace(0.1, 1.0, 5)`.

**Returns**

- **train_scores** (*list of float*) – The scores for the training set.
- **test_scores** (*list of float*) – The scores on the test set.
- **num_examples** (*list of int*) – The numbers of training examples used to generate the curve

**load** (*learner_path*)

Replace the current learner instance with a saved learner.
**Parameters**

learner_path *(str)* – The path to a saved learner object file to load.

**model**

The underlying scikit-learn model

**model_kwargs**

A dictionary of the underlying scikit-learn model’s keyword arguments

**model_params**

Model parameters (i.e., weights) for a LinearModel (e.g., Ridge) regression and liblinear models. If the model was trained using feature hashing, then names of the form hashed_feature_XX are used instead.

**Returns**

- **res** *(dict)* – A dictionary of labeled weights.
- **intercept** *(dict)* – A dictionary of intercept(s).

**Raises**

ValueError – If the instance does not support model parameters.

**model_type**

The model type (i.e., the class)

**predict** *(examples, prediction_prefix=None, append=False, class_labels=False)*

Uses a given model to generate predictions on a given FeatureSet.

**Parameters**

- **examples** *(skll.FeatureSet)* – The FeatureSet instance to predict labels for.
- **prediction_prefix** *(str, optional)* – If saving the predictions, this is the prefix that will be used for the filename. It will be followed by ".predictions.tsv" Defaults to None.
- **append** *(bool, optional)* – Should we append the current predictions to the file if it exists? Defaults to False.
- **class_labels** *(bool, optional)* – For classifier, should we convert class indices to their (str) labels for the returned array? Note that class labels are always written out to disk. Defaults to False.

**Returns**

**yhat** – The predictions returned by the Learner instance.

**Return type**

array-like

**Raises**

MemoryError – If process runs out of memory when converting to dense.

**probability**

Should learner return probabilities of all labels (instead of just label with highest probability)?
save (learner_path)

Save the Learner instance to a file.

Parameters
learner_path (str) – The path to save the Learner instance to.

train (examples, param_grid=None, grid_search_folds=3, grid_search=True, grid_objective=None, grid_jobs=None, shuffle=False, create_label_dict=True)

Train a classification model and return the model, score, feature vectorizer, scaler, label dictionary, and inverse label dictionary.

Parameters

- examples (skll.FeatureSet) – The FeatureSet instance to use for training.
- param_grid (list of dicts, optional) – The parameter grid to search through for grid search. If None, a default parameter grid will be used. Defaults to None.
- grid_search_folds (int or dict, optional) – The number of folds to use when doing the grid search, or a mapping from example IDs to folds. Defaults to 3.
- grid_search (bool, optional) – Should we do grid search? Defaults to True.
- grid_objective (str, optional) – The name of the objective function to use when doing the grid search. Must be specified if grid_search is True. Defaults to None.
- grid_jobs (int, optional) – The number of jobs to run in parallel when doing the grid search. If None or 0, the number of grid search folds will be used. Defaults to None.
- shuffle (bool, optional) – Shuffle examples (e.g., for grid search CV.) Defaults to False.
- create_label_dict (bool, optional) – Should we create the label dictionary? This dictionary is used to map between string labels and their corresponding numerical values. This should only be done once per experiment, so when cross_validate calls train, create_label_dict gets set to False. This option is only for internal use. Defaults to True.

Returns

tuple – 1) The best grid search objective function score, or 0 if we’re not doing grid search, and 2) a dictionary of grid search CV results with keys such as “params”, “mean_test_score”, etc, that are mapped to lists of values associated with each hyperparameter set combination, or None if not doing grid search.
**Return type** (float, dict)

**Raises**

- ValueError – If grid_objective is not a valid grid objective or if one is not specified when necessary.
- MemoryError – If process runs out of memory converting training data to dense.
- ValueError – If FeatureHasher is used with MultinomialNB.

**From metrics Module**

```python
calculate_f1_score_least_frequent(y_true, y_pred)
```
Calculate the F1 score of the least frequent label/class in `y_true` for `y_pred`.

**Parameters**

- `y_true` (array-like of float) – The true/actual/gold labels for the data.
- `y_pred` (array-like of float) – The predicted/observed labels for the data.

**Returns**

- `ret_score` – F1 score of the least frequent label.

**Return type** float

```python
calculate_kappa(y_true, y_pred, weights=None, allow_off_by_one=False)
```
Calculates the kappa inter-rater agreement between two the gold standard and the predicted ratings. Potential values range from -1 (representing complete disagreement) to 1 (representing complete agreement). A kappa value of 0 is expected if all agreement is due to chance.

In the course of calculating kappa, all items in `y_true` and `y_pred` will first be converted to floats and then rounded to integers.

It is assumed that `y_true` and `y_pred` contain the complete range of possible ratings.

This function contains a combination of code from yorchopolis’s kappa-stats and Ben Hamner’s Metrics projects on Github.

**Parameters**

- `y_true` (array-like of float) – The true/actual/gold labels for the data.
- `y_pred` (array-like of float) – The predicted/observed labels for the data.
• **weights** *(str or np.array, optional)* – Specifies the weight matrix for the calculation. Options are

- **None** = unweighted-kappa
- 'quadratic' = quadratic-weighted kappa
- 'linear' = linear-weighted kappa
- two-dimensional numpy array = a custom matrix of weights. Each weight corresponds to the \( w_{ij} \) values in the wikipedia description of how to calculate weighted Cohen’s kappa. Defaults to None.

• **allow_off_by_one** *(bool, optional)* – If true, ratings that are off by one are counted as equal, and all other differences are reduced by one. For example, 1 and 2 will be considered to be equal, whereas 1 and 3 will have a difference of 1 for when building the weights matrix. Defaults to False.

**Returns** k – The kappa score, or weighted kappa score.

**Return type** float

**Raises**

- **AssertionError** – If y_true != y_pred.
- **ValueError** – If labels cannot be converted to int.
- **ValueError** – If invalid weight scheme.

`skll.correlation(y_true, y_pred, corr_type='pearson')`  
Calculate given correlation between `y_true` and `y_pred`. `y_pred` can be multi-dimensional. If `y_pred` is 1-dimensional, it may either contain probabilities, most-likely classification labels, or regressor predictions. In that case, we simply return the correlation between `y_true` and `y_pred`. If `y_pred` is multi-dimensional, it contains probabilities for multiple classes in which case, we infer the most likely labels and then compute the correlation between those and `y_true`.

**Parameters**

- **y_true** *(array-like of float)* – The true/actual/gold labels for the data.

- **y_pred** *(array-like of float)* – The predicted/observed labels for the data.

- **corr_type** *(str, optional)* – Which type of correlation to compute. Possible choices are pearson, spearman, and kendall_tau. Defaults to pearson.

**Returns** ret_score – correlation value if well-defined, else 0.0
Return type float

1.6.3 data Package

data.featureset Module

Classes related to storing/merging feature sets.

author Dan Blanchard (dblanchard@ets.org)
author Nitin Madnani (nmadnani@ets.org)
author Jeremy Biggs (jbiggs@ets.org)
organization ETS

class skll.data.featureset.FeatureSet (name, ids, labels=None, features=None, vectorizer=None)

Encapsulation of all of the features, values, and metadata about a given set of data. This replaces ExamplesTuple from older versions of SKLL.

Parameters

- **name (str)** – The name of this feature set.
- **ids (np.array)** – Example IDs for this set.
- **labels (np.array, optional)** – labels for this set. Defaults to None.
- **feature (list of dict or array-like, optional)** – The features for each instance represented as either a list of dictionaries or an array-like (if vectorizer is also specified). Defaults to None.
- **vectorizer (DictVectorizer or FeatureHasher, optional)** – Vectorizer which will be used to generate the feature matrix. Defaults to None.

Warning: FeatureSets can only be equal if the order of the instances is identical because these are stored as lists/arrays. Since scikit-learn’s DictVectorizer automatically sorts the underlying feature matrix if it is sparse, we do not do any sorting before checking for equality. This is not a problem because we _always_ use sparse matrices with DictVectorizer when creating FeatureSets.
Notes

If ids, labels, and/or features are not None, the number of rows in each array must be equal.

**filter** *(ids=None, labels=None, features=None, inverse=False)*

Removes or keeps features and/or examples from the Featureset depending on the parameters. Filtering is done in-place.

**Parameters**

- **ids** *(list of str/float, optional)* – Examples to keep in the FeatureSet. If None, no ID filtering takes place. Defaults to None.
- **labels** *(list of str/float, optional)* – Labels that we want to retain examples for. If None, no label filtering takes place. Defaults to None.
- **features** *(list of str, optional)* – Features to keep in the FeatureSet. To help with filtering string-valued features that were converted to sequences of boolean features when read in, any features in the FeatureSet that contain a = will be split on the first occurrence and the prefix will be checked to see if it is in features. If None, no feature filtering takes place. Cannot be used if FeatureSet uses a FeatureHasher for vectorization. Defaults to None.
- **inverse** *(bool, optional)* – Instead of keeping features and/or examples in lists, remove them. Defaults to False.

**Raises** ValueError – If attempting to use features to filter a FeatureSet that uses a FeatureHasher vectorizer.

**filtered_iter** *(ids=None, labels=None, features=None, inverse=False)*

A version of **__iter__** that retains only the specified features and/or examples from the output.

**Parameters**

- **ids** *(list of str/float, optional)* – Examples to keep in the FeatureSet. If None, no ID filtering takes place. Defaults to None.
- **labels** *(list of str/float, optional)* – Labels that we want to retain examples for. If None, no label filtering takes place. Defaults to None.
- **features** *(list of str, optional)* – Features to keep in the FeatureSet. To help with filtering string-valued features that were converted to sequences of boolean features when read in, any features in the FeatureSet that contain a = will be split on the first occurrence and the prefix will be checked to see if it is in features. If
None, no feature filtering takes place. Cannot be used if FeatureSet uses a FeatureHasher for vectorization. Defaults to None.

- **inverse** (bool, optional) – Instead of keeping features and/or examples in lists, remove them. Defaults to False.

Yields

- **id_** (str) – The ID of the example.
- **label_** (str) – The label of the example.
- **feat_dict** (dict) – The feature dictionary, with feature name as the key and example value as the value.

Raises ValueError – If the vectorizer is not a DictVectorizer.

```python
def from_data_frame(df, name=None, labels_column=None, vectorizer=None):
    # Helper function to create a FeatureSet instance from a pandas.DataFrame. Will raise an Exception if pandas is not installed in your environment. The ids in the FeatureSet will be the index from the given frame.
    # Parameters
    # - df (pd.DataFrame) – The pandas.DataFrame object to use as a FeatureSet.
    # - name (str) – The name of the output FeatureSet instance.
    # - labels_column (str, optional) – The name of the column containing the labels (data to predict). Defaults to None.
    # - vectorizer (DictVectorizer or FeatureHasher, optional) – Vectorizer which will be used to generate the feature matrix. Defaults to None.
    # Returns feature_set – A FeatureSet instance generated from the given data frame.
    # Return type skll.FeatureSet
```

```python
has_labels
Check if FeatureSet has finite labels.

    Returns has_labels – Whether or not this FeatureSet has any finite labels.
    Return type bool
```

```python
def split_by_ids(fs, ids_for_split1, ids_for_split2=None):
    # Split the FeatureSet into two new FeatureSet instances based on the given IDs for the two splits.
    # Parameters
    # - fs (skll.FeatureSet) – The FeatureSet instance to split.
```
**ids_for_split1** (list of int) – A list of example IDs which will be split out into the first FeatureSet instance. Note that the FeatureSet instance will respect the order of the specified IDs.

**ids_for_split2** (list of int, optional) – An optional list of example IDs which will be split out into the second FeatureSet instance. Note that the FeatureSet instance will respect the order of the specified IDs. If this is not specified, then the second FeatureSet instance will contain the complement of the first set of IDs sorted in ascending order. Defaults to None.

**Returns**

- **fs1** (skll.FeatureSet) – The first FeatureSet.
- **fs2** (skll.FeatureSet) – The second FeatureSet.

### data.readers Module

This module handles loading data from various types of data files. A base Reader class is provided that is sub-classed for each data file type that is supported, e.g. CSVReader.

### Notes about IDs & Label Conversion

All Reader sub-classes are designed to read in example IDs as strings unless **ids_to_floats** is set to True in which case they will be read in as floats, if possible. In the latter case, an exception will be raised if they cannot be converted to floats.

All Reader sub-classes also use the **safe_float** function internally to read in labels. This function tries to convert a single label first to int, then to float. If neither conversion is possible, the label remains a str. It should be noted that, if classification is being done with a feature set that is read in with one of the Reader sub-classes, care must be taken to ensure that labels do not get converted in unexpected ways. For example, classification labels should not be a mixture of int-converting and float-converting labels. Consider the situation below:

```python
>>> import numpy as np
>>> from skll.data.readers import safe_float
>>> np.array([safe_float(x) for x in ["2", "2.2", "2.21"]])  # array([2.0, 2.2, 2.21])
```

The labels will all be converted to floats and any classification model generated with this data will predict labels such as 2.0, 2.2, etc., not str values that exactly match the input labels, as might be expected. Be aware that it may be best to make use of the **class_map** keyword argument in such cases to map original labels to labels that convert only to str.

**author** Dan Blanchard (dblanchard@ets.org)
class skll.data.readers.ARFFReader(path_or_list, **kwargs)

Bases: skll.data.readers.DelimitedReader

Reader for creating a FeatureSet instance from an ARFF file. If example/instance IDs are included in the files, they must be specified in the id column. Also, there must be a column with the name specified by label_col if the data is labeled, and this column must be the final one (as it is in Weka).

Parameters

- **path_or_list (str)** – The path to the ARFF file.
- **kwargs (dict, optional)** – Other arguments to the Reader object.

static split_with_quotes(string, delimiter=' ', quote_char='"', escape_char='\')

A replacement for string.split that won’t split delimiters enclosed in quotes.

Parameters

- **string (str)** – The string with quotes to split
- **delimiter (str, optional)** – The delimiter to split on. Defaults to ' '.
- **quote_char (str, optional)** – The quote character to ignore. Defaults to '"'.
- **escape_char (str, optional)** – The escape character. Defaults to '\'.

class skll.data.readers.CSVReader(path_or_list, replace_blanks_with=None, drop_blanks=False, pandas_kwargs=None, **kwargs)

Bases: skll.data.readers.Reader

Reader for creating a FeatureSet instance from a CSV file. If example/instance IDs are included in the files, they must be specified in the id column. Also, there must be a column with the name specified by label_col if the data is labeled.

Parameters

- **path_or_list (str)** – The path to a comma-delimited file.
- **replace_blanks_with** (value, dict, or None, optional) – Specifies a new value with which to replace blank values. Options are

- value = A (numeric) value with which to replace blank values.
- dict = A dictionary specifying the replacement value for each column.
- None = Blank values will be left as blanks, and not replaced.

The replacement occurs after the data set is read into a `pd.DataFrame`. Defaults to None.

- **drop_blanks** (bool, optional) – If True, remove lines/rows that have any blank values. These lines/rows are removed after the data set is read into a `pd.DataFrame`. Defaults to False.

- **pandas_kwargs** (dict or None, optional) – Arguments that will be passed directly to the pandas I/O reader. Defaults to None.

- **kwargs** (dict, optional) – Other arguments to the Reader object.

```python
class skll.data.readers.DelimitedReader(path_or_list, **kwargs)
Bases: skll.data.readers.Reader
```

Reader for creating a FeatureSet instance from a delimited (CSV/TSV) file. If example-instance IDs are included in the files, they must be specified in the id column. For ARFF, CSV, and TSV files, there must be a column with the name specified by label_col if the data is labeled. For ARFF files, this column must also be the final one (as it is in Weka).

**Parameters**

- **path_or_list** (str) – The path to a delimited file.
- **dialect** (str) – The dialect of to pass on to the underlying CSV reader. Defaults to 'excel-tab'.
- **kwargs** (dict, optional) – Other arguments to the Reader object.

```python
class skll.data.readers.DictListReader(path_or_list, quiet=True, ids_to_floats=False, label_col='y', id_col='id', class_map=None, sparse=True, feature_hasher=False, num_features=None, logger=None)
Bases: skll.data.readers.Reader
```

This class is to facilitate programmatic use of Learner.predict() and other methods that take FeatureSet objects as input. It iterates over examples in the same way as other Reader classes, but uses a list of example dictionaries instead of a path to a file.
read()

Read examples from list of dictionaries.

**Returns** feature_set – FeatureSet representing the list of dictionaries we read in.

**Return type** `skll.FeatureSet`

class skll.data.readers.LibSVMReader(path_or_list, quiet=True, 
ids_to_floats=False, label_col='y', 
id_col='id', class_map=None, sparse=True, 
feature_hasher=False, num_features=None, logger=None)

Bases: `skll.data.readers.Reader`

Reader to create a FeatureSet instance from a LibSVM/LibLinear/SVMLight file. We use a specially formatted comment for storing example IDs, class names, and feature names, which are normally not supported by the format. The comment is not mandatory, but without it, your labels and features will not have names. The comment is structured as follows:

| ExampleID | 1=FirstClass | 1=FirstFeature 2=SecondFeature |

class skll.data.readers.MegaMReader(path_or_list, quiet=True, 
ids_to_floats=False, label_col='y', 
id_col='id', class_map=None, sparse=True, feature_hasher=False, 
um_features=None, logger=None)

Bases: `skll.data.readers.Reader`

Reader to create a FeatureSet instance from a MegaM -fvals file. If example/instance IDs are included in the files, they must be specified as a comment line directly preceding the line with feature values.

class skll.data.readers.NDJReader(path_or_list, quiet=True, 
ids_to_floats=False, label_col='y', 
id_col='id', class_map=None, sparse=True, feature_hasher=False, 
um_features=None, logger=None)

Bases: `skll.data.readers.Reader`

Reader to create a FeatureSet instance from a JSONlines/NDJ file. If example/instance IDs are included in the files, they must be specified as the “id” key in each JSON dictionary.

class skll.data.readers.Reader(path_or_list, quiet=True, 
ids_to_floats=False, label_col='y', 
id_col='id', class_map=None, sparse=True, feature_hasher=False, num_features=None, logger=None)
Bases: object

A helper class to make picklable iterators out of example dictionary generators.

**Parameters**

- **path_or_list** *(str or list of dict)* – Path or a list of example dictionaries.
- **quiet** *(bool, optional)* – Do not print “Loading...” status message to stderr. Defaults to True.
- **ids_to_floats** *(bool, optional)* – Convert IDs to float to save memory. Will raise error if we encounter a non-numeric ID. Defaults to False.
- **label_col** *(str, optional)* – Name of the column which contains the class labels for ARFF/CSV/TSV files. If no column with that name exists, or None is specified, the data is considered to be unlabelled. Defaults to 'y'.
- **id_col** *(str, optional)* – Name of the column which contains the instance IDs. If no column with that name exists, or None is specified, example IDs will be automatically generated. Defaults to 'id'.
- **class_map** *(dict, optional)* – Mapping from original class labels to new ones. This is mainly used for collapsing multiple labels into a single class. Anything not in the mapping will be kept the same. Defaults to None.
- **sparse** *(bool, optional)* – Whether or not to store the features in a numpy CSR matrix when using a DictVectorizer to vectorize the features. Defaults to True.
- **feature_hasher** *(bool, optional)* – Whether or not a FeatureHasher should be used to vectorize the features. Defaults to False.
- **num_features** *(int, optional)* – If using a FeatureHasher, how many features should the resulting matrix have? You should set this to a power of 2 greater than the actual number of features to avoid collisions. Defaults to None.
- **logger** *(logging.Logger, optional)* – A logger instance to use to log messages instead of creating a new one by default. Defaults to None.

**classmethod for_path** *(path_or_list, **kwargs)*

Instantiate the appropriate Reader sub-class based on the file extension of the given path. Or use a dictionary reader if the input is a list of dictionaries.

**Parameters**
SciKit-Learn Laboratory Documentation, Release 2.1

- **path_or_list** (*str or list of dicts*) – A path or list of example dictionaries.

- **kwargs** (*dict, optional*) – The arguments to the Reader object being instantiated.

Returns **reader** – A new instance of the Reader sub-class that is appropriate for the given path.

Return type **skll.Reader**

Raises **ValueError** – If file does not have a valid extension.

**read()**

Loads examples in the `.arff`, `.csv`, `.jsonlines`, `.libsvm`, `.megam`, `.ndj`, or `.tsv` formats.

Returns **feature_set** – FeatureSet instance representing the input file.

Return type **skll.FeatureSet**

Raises

- **ValueError** – If `ids_to_floats` is True, but IDs cannot be converted.

- **ValueError** – If no features are found.

- **ValueError** – If the example IDs are not unique.

**class** **skll.data.readers.TSVReader** (*path_or_list, replace_blanks_with=None, drop_blanks=False, pandas_kwargs=None, **kwargs*)

Bases: **skll.data.readers.CSVReader**

Reader for creating a FeatureSet instance from a TSV file. If exampleINSTANCE IDs are included in the files, they must be specified in the id column. Also there must be a column with the name specified by `label_col` if the data is labeled.

**Parameters**

- **path_or_list** (*str*) – The path to a comma-delimited file.

- **replace_blanks_with** (*value, dict, or None, optional*) – Specifies a new value with which to replace blank values. Options are

  - `value` = A (numeric) value with which to replace blank values.
  - `dict` = A dictionary specifying the replacement value for each column.
  - `None` = Blank values will be left as blanks, and not replaced.
The replacement occurs after the data set is read into a `pd.DataFrame`. Defaults to `None`.

- **drop_blanks (bool, optional)** – If True, remove lines/rows that have any blank values. These lines/rows are removed after the the data set is read into a `pd.DataFrame`. Defaults to `False`.

- **pandas_kwargs (dict or None, optional)** – Arguments that will be passed directly to the `pandas` I/O reader. Defaults to `None`.

- **kwargs (dict, optional)** – Other arguments to the Reader object.

```
skll.data.readers.safe_float (text, replace_dict=None, logger=None)
```

Attempts to convert a string to an int, and then a float, but if neither is possible, returns the original string value.

**Parameters**

- **text (str)** – The text to convert.

- **replace_dict (dict, optional)** – Mapping from text to replacement text values. This is mainly used for collapsing multiple labels into a single class. Replacing happens before conversion to floats. Anything not in the mapping will be kept the same. Defaults to `None`.

- **logger (logging.Logger)** – The Logger instance to use to log messages. Used instead of creating a new Logger instance by default. Defaults to `None`.

**Returns**

- **text** – The text value converted to int or float, if possible

**Return type** int or float or str

```
data.writers Module
```

Handles loading data from various types of data files.

**author** Dan Blanchard (dblanchard@ets.org)

**author** Michael Heilman (mheilman@ets.org)

**author** Nitin Madnani (nmadnani@ets.org)

**author** Jeremy Biggs (jbiggs@ets.org)

**organization** ETS

```
class skll.data.writers.ARFFWriter (path, feature_set, **kwargs)
```

Writer for writing out FeatureSets as ARFF files.

**Parameters**
• **path**(str) – A path to the feature file we would like to create. If `subsets` is not `None`, this is assumed to be a string containing the path to the directory to write the feature files with an additional file extension specifying the file type. For example `/foo/.arff`.

• **feature_set**(skll.FeatureSet) – The FeatureSet instance to dump to the output file.

• **relation**(str, optional) – The name of the relation in the ARFF file. Defaults to 'skll_relation'.

• **regression**(bool, optional) – Is this an ARFF file to be used for regression? Defaults to `False`.

• **kwargs**(dict, optional) – The arguments to the Writer object being instantiated.

```python
class skll.data.writers.CSVWriter(path, feature_set, pandas_kwargs=None, **kwargs)
Bases: skll.data.writers.Writer
```

Writer for writing out FeatureSet instances as CSV files.

**Parameters**

• **path**(str) – A path to the feature file we would like to create. If `subsets` is not `None`, this is assumed to be a string containing the path to the directory to write the feature files with an additional file extension specifying the file type. For example `/foo/.csv`.

• **feature_set**(skll.FeatureSet) – The FeatureSet instance to dump to the output file.

• **pandas_kwargs**(dict or `None`, optional) – Arguments that will be passed directly to the pandas I/O reader. Defaults to `None`.

• **kwargs**(dict, optional) – The arguments to the Writer object being instantiated.

```python
class skll.data.writers.LibSVMWriter(path, feature_set, **kwargs)
Bases: skll.data.writers.Writer
```

Writer for writing out FeatureSets as LibSVM/SVMLight files.

**Parameters**

• **path**(str) – A path to the feature file we would like to create. If `subsets` is not `None`, this is assumed to be a string containing the path to the directory to write the feature files with an additional file extension specifying the file type. For example `/foo/.libsvm`.

• **feature_set**(skll.FeatureSet) – The FeatureSet instance to dump to the output file.
• **kwargs (dict, optional) – The arguments to the Writer object being instantiated.

class skll.data.writers.MegaMWriter(path, feature_set, **kwargs)
Bases: skll.data.writers.Writer

Writer for writing out FeatureSets as MegaM files.

class skll.data.writers.NDJWriter(path, feature_set, **kwargs)
Bases: skll.data.writers.Writer

Writer for writing out FeatureSets as .jsonlines/.ndj files.

Parameters

• **path (str) – A path to the feature file we would like to create. If
subsets is not None, this is assumed to be a string containing the path
to the directory to write the feature files with an additional file extension
specifying the file type. For example /foo/.ndj.

• **feature_set (skll.FeatureSet) – The FeatureSet instance
dump to the output file.

• **kwargs (dict, optional) – The arguments to the Writer object
being instantiated.

class skll.data.writers.TSVWriter(path, feature_set, pandas_kwargs=None, **kwargs)
Bases: skll.data.writers.CSVWriter

Writer for writing out FeatureSets as TSV files.

Parameters

• **path (str) – A path to the feature file we would like to create. If
subsets is not None, this is assumed to be a string containing the path
to the directory to write the feature files with an additional file extension
specifying the file type. For example /foo/.tsv.

• **feature_set (skll.FeatureSet) – The FeatureSet instance
dump to the output file.

• **pandas_kwargs (dict or None, optional) – Arguments that
will be passed directly to the pandas I/O reader. Defaults to None.

• **kwargs (dict, optional) – The arguments to the Writer object
being instantiated.

class skll.data.writers.Writer(path, feature_set, **kwargs)
Bases: object

Helper class for writing out FeatureSets to files on disk.

Parameters
• **path** *(str)* – A path to the feature file we would like to create. The suffix to this filename must be `.arff`, `.csv`, `.jsonlines`, `.libsvm`, `.megam`, `.ndj`, or `.tsv`. If `subsets` is not `None`, when calling the `write()` method, path is assumed to be a string containing the path to the directory to write the feature files with an additional file extension specifying the file type. For example `/foo/.csv`.

• **feature_set** *(skll.FeatureSet)* – The `FeatureSet` instance to dump to the file.

• **quiet** *(bool)* – Do not print “Writing...” status message to stderr. Defaults to `True`.

• **subsets** *(dict (str to list of str))* – A mapping from subset names to lists of feature names that are included in those sets. If given, a feature file will be written for every subset (with the name containing the subset name as suffix to `path`). Note, since string-valued features are automatically converted into boolean features with names of the form `FEATURE_NAME=STRING_VALUE`, when doing the filtering, the portion before the `=` is all that’s used for matching. Therefore, you do not need to enumerate all of these boolean feature names in your mapping. Defaults to `None`.

• **logger** *(logging.Logger)* – A logger instance to use to log messages instead of creating a new one by default. Defaults to `None`.

### classmethod for_path *(path, feature_set, **kwargs)*

Retrieve object of `Writer` sub-class that is appropriate for given path.

**Parameters**

• **path** *(str)* – A path to the feature file we would like to create. The suffix to this filename must be `.arff`, `.csv`, `.jsonlines`, `.libsvm`, `.megam`, `.ndj`, or `.tsv`. If `subsets` is not `None`, when calling the `write()` method, path is assumed to be a string containing the path to the directory to write the feature files with an additional file extension specifying the file type. For example `/foo/.csv`.

• **feature_set** *(skll.FeatureSet)* – The `FeatureSet` instance to dump to the output file.

• **kwargs** *(dict)* – The keyword arguments for `for_path` are the same as the initializer for the desired `Writer` subclass.

**Returns** `writer` – New instance of the `Writer` sub-class that is appropriate for the given path.

**Return type** `skll.data.writers.Writer`

**write()**

Writes out this `Writer`’s `FeatureSet` to a file in its format.
1.6.4 experiments Module

Functions related to running experiments and parsing configuration files.

**author** Dan Blanchard (dblanchard@ets.org)
**author** Michael Heilman (mheilman@ets.org)
**author** Nitin Madnani (nmadnani@ets.org)
**author** Chee Wee Leong (cleong@ets.org)

```python
class skll.experiments.NumpyTypeEncoder(*, skipkeys=False,
    ensure_ascii=True,
    check_circular=True,
    allow_nan=True,
    sort_keys=False, indent=None,
    separators=None)
```

Bases: json.encoder.JSONEncoder

This class is used when serializing results, particularly the input label values if the input has int-valued labels. Numpy int64 objects can’t be serialized by the json module, so we must convert them to int objects.

A related issue where this was adapted from: https://stackoverflow.com/questions/11561932/why-does-json-dumpslistnp-arange5-fail-while-json-dumpsnp-arange5-tolis

**default**(obj)

Implement this method in a subclass such that it returns a serializable object for o, or calls the base implementation (to raise a TypeError).

For example, to support arbitrary iterators, you could implement default like this:

```python
def default(self, o):
    try:
        iterable = iter(o)
    except TypeError:
        pass
    else:
        return list(iterable)

# Let the base class default method raise the TypeError
return JSONEncoder.default(self, o)
```

```python
skll.experiments.run_configuration(config_file, local=False, overwrite=True, queue='all.q', hosts=None, write_summary=True, quiet=False, ablation=0, resume=False, log_level=20)
```

Takes a configuration file and runs the specified jobs on the grid.
Parameters

- **config_file** *(str)* – Path to the configuration file we would like to use.

- **local** *(bool, optional)* – Should this be run locally instead of on the cluster? Defaults to False.

- **overwrite** *(bool, optional)* – If the model files already exist, should we overwrite them instead of re-using them? Defaults to True.

- **queue** *(str, optional)* – The DRMAA queue to use if we’re running on the cluster. Defaults to 'all.q'.

- **hosts** *(list of str, optional)* – If running on the cluster, these are the machines we should use. Defaults to None.

- **write_summary** *(bool, optional)* – Write a TSV file with a summary of the results. Defaults to True.

- **quiet** *(bool, optional)* – Suppress printing of “Loading…” messages. Defaults to False.

- **ablation** *(int, optional)* – Number of features to remove when doing an ablation experiment. If positive, we will perform repeated ablation runs for all combinations of features removing the specified number at a time. If None, we will use all combinations of all lengths. If 0, the default, no ablation is performed. If negative, a ValueError is raised. Defaults to 0.

- **resume** *(bool, optional)* – If result files already exist for an experiment, do not overwrite them. This is very useful when doing a large ablation experiment and part of it crashes. Defaults to False.

- **log_level** *(str, optional)* – The level for logging messages. Defaults to logging.INFO.

Returns **result_json_paths** – A list of paths to .json results files for each variation in the experiment.

**Return type** list of str

**Raises**

- ValueError – If value for "ablation" is not a positive int or None.

- OSError – If the length of the FeatureSet name > 210.

1.6.5 learner Module

Provides easy-to-use wrapper around scikit-learn.
class `skll.learner.Densifier`

Bases: `sklearn.base.BaseEstimator`, `sklearn.base.TransformerMixin`

A custom pipeline stage that will be inserted into the learner pipeline attribute to accommodate the situation when SKLL needs to manually convert feature arrays from sparse to dense. For example, when features are being hashed but we are also doing centering using the feature means.

```python
fit_transform(X, y=None)
```

Fit to data, then transform it.

Fits transformer to X and y with optional parameters fit_params and returns a transformed version of X.

**Parameters**

- `X` *(numpy array of shape [n_samples, n_features]*)
  - Training set.
- `y` *(numpy array of shape [n_samples]*)
  - Target values.
- `**fit_params` *(dict)*
  - Additional fit parameters.

**Returns**

- `X_new` – Transformed array.

**Return type**

numpy array of shape [n_samples, n_features_new]

class `skll.learner.FilteredLeaveOneGroupOut` *(keep, example_ids, logger=None)*

Bases: `sklearn.model_selection._split.LeaveOneGroupOut`

Version of `LeaveOneGroupOut` cross-validation iterator that only outputs indices of instances with IDs in a prespecified set.

**Parameters**

- `keep` *(set of str)*
  - A set of IDs to keep.
- `example_ids` *(list of str, of length n_samples)*
  - A list of example IDs.

```python
split(X, y, groups)
```

Generate indices to split data into training and test set.

**Parameters**
X (array-like, with shape (n_samples, n_features)) – Training data, where n_samples is the number of samples and n_features is the number of features.

y (array-like, of length n_samples) – The target variable for supervised learning problems.

groups (array-like, with shape (n_samples,)) – Group labels for the samples used while splitting the dataset into train/test set.

Yields

- train_index (np.array) – The training set indices for that split.
- test_index (np.array) – The testing set indices for that split.

```python
class skll.learner.Learner(model_type, probability=False, pipeline=False, feature_scaling='none', model_kwargs=None, pos_label_str=None, min_feature_count=1, sampler=None, sampler_kwargs=None, custom_learner_path=None, logger=None)
```

Bases: object

A simpler learner interface around many scikit-learn classification and regression functions.

Parameters

- **model_type** (str) – Name of estimator to create (e.g., 'LogisticRegression'). See the skll package documentation for valid options.

- **probability** (bool, optional) – Should learner return probabilities of all labels (instead of just label with highest probability)? Defaults to False.

- **pipeline** (bool, optional) – Should learner contain a pipeline attribute that contains a scikit-learn Pipeline object composed of all steps including the vectorizer, the feature selector, the sampler, the feature scaler, and the actual estimator. Note that this will increase the size of the learner object in memory and also when it is saved to disk. Defaults to False.

- **feature_scaling** (str, optional) – How to scale the features, if at all. Options are - 'with_std': scale features using the standard deviation - 'with_mean': center features using the mean - 'both': do both scaling as well as centering - 'none': do neither scaling nor centering. Defaults to ‘none’.

- **model_kwargs** (dict, optional) – A dictionary of keyword arguments to pass to the initializer for the specified model. Defaults to
• **pos_label_str** *(str, optional)* – A string denoting the label of the class to be treated as the positive class in a binary classification setting. If `None`, the class represented by the label that appears second when sorted is chosen as the positive class. For example, if the two labels in data are “A” and “B” and `pos_label_str` is not specified, “B” will be chosen as the positive class. Defaults to `None`.

• **min_feature_count** *(int, optional)* – The minimum number of examples a feature must have a nonzero value in to be included. Defaults to `1`.

• **sampler** *(str, optional)* – The sampler to use for kernel approximation, if desired. Valid values are - ‘AdditiveChi2Sampler’ - ‘Nystroem’ - ‘RBFSampler’ - ‘SkewedChi2Sampler’ Defaults to `None`.

• **sampler_kwargs** *(dict, optional)* – A dictionary of keyword arguments to pass to the initializer for the specified sampler. Defaults to `None`.

• **custom_learner_path** *(str, optional)* – Path to module where a custom classifier is defined. Defaults to `None`.

• **logger** *(logging object, optional)* – A logging object. If `None` is passed, get logger from `__name__`. Defaults to `None`.

**cross_validate** *(examples, stratified=True, cv_folds=10, grid_search=True, grid_search_folds=3, grid_jobs=None, grid_objective=None, output_metrics=[], prediction_prefix=None, param_grid=None, shuffle=False, save_cv_folds=False, save_cv_models=False, use_custom_folds_for_grid_search=True)*

Cross-validates a given model on the training examples.

**Parameters**

• **examples** *(skll.FeatureSet)* – The FeatureSet instance to cross-validate learner performance on.

• **stratified** *(bool, optional)* – Should we stratify the folds to ensure an even distribution of labels for each fold? Defaults to `True`.

• **cv_folds** *(int, optional)* – The number of folds to use for cross-validation, or a mapping from example IDs to folds. Defaults to `10`.

• **grid_search** *(bool, optional)* – Should we do grid search when training each fold? Note: This will make this take *much* longer. Defaults to `False`. 
• **grid_search_folds** *(int or dict, optional)* – The number of folds to use when doing the grid search, or a mapping from example IDs to folds. Defaults to 3.

• **grid_jobs** *(int, optional)* – The number of jobs to run in parallel when doing the grid search. If None or 0, the number of grid search folds will be used. Defaults to None.

• **grid_objective** *(str, optional)* – The name of the objective function to use when doing the grid search. Must be specified if grid_search is True. Defaults to None.

• **output_metrics** *(list of str, optional)* – List of additional metric names to compute in addition to the metric used for grid search. Empty by default. Defaults to an empty list.

• **prediction_prefix** *(str, optional)* – If saving the predictions, this is the prefix that will be used for the filename. It will be followed by "_predictions.tsv" Defaults to None.

• **param_grid** *(list of dicts, optional)* – The parameter grid to traverse. Defaults to None.

• **shuffle** *(bool, optional)* – Shuffle examples before splitting into folds for CV. Defaults to False.

• **save_cv_folds** *(bool, optional)* – Whether to save the cv fold ids or not? Defaults to False.

• **save_cv_models** *(bool, optional)* – Whether to save the cv models or not? Defaults to False.

• **use_custom_folds_for_grid_search** *(bool, optional)* – If cv_folds is a custom dictionary, but grid_search_folds is not, perhaps due to user oversight, should the same custom dictionary automatically be used for the inner grid-search cross-validation? Defaults to True.

**Returns**

• **results** *(list of 6-tuples)* – The confusion matrix, overall accuracy, per-label PRFs, model parameters, objective function score, and evaluation metrics (if any) for each fold.

• **grid_search_scores** *(list of floats)* – The grid search scores for each fold.

• **grid_search_cv_results_dicts** *(list of dicts)* – A list of dictionaries of grid search CV results, one per fold, with keys such as “params”, “mean_test_score”, etc, that are mapped to lists of values associated with each hyperparameter set combination.
• **skll_fold_ids** (*dict*) – A dictionary containing the test-fold number for each id if `save_cv_folds` is True, otherwise None.

• **models** (*list of skll.learner.Learner*) – A list of skll.learner.Learners, one for each fold if `save_cv_models` is True, otherwise None.

**Raises** `ValueError` – If labels are not encoded as strings.

### `evaluate`(*examples*, prediction_prefix=None, append=False, grid_objective=None, output_metrics=[]) Evaluates a given model on a given dev or test FeatureSet.

**Parameters**

• **examples** (*skll.FeatureSet*) – The FeatureSet instance to evaluate the performance of the model on.

• **prediction_prefix** (*str, optional*) – If saving the predictions, this is the prefix that will be used for the filename. It will be followed by "_predictions.tsv". Defaults to None.

• **append** (*bool, optional*) – Should we append the current predictions to the file if it exists? Defaults to False.

• **grid_objective** (*function, optional*) – The objective function that was used when doing the grid search. Defaults to None.

• **output_metrics** (*list of str, optional*) – List of additional metric names to compute in addition to grid objective. Empty by default. Defaults to an empty list.

**Returns** *res* – The confusion matrix, the overall accuracy, the per-label PRFs, the model parameters, the grid search objective function score, and the additional evaluation metrics, if any.

**Return type** 6-tuple

### `classmethod from_file`(*learner_path*, logger=None) Load a saved Learner instance from a file path.

**Parameters**

• **learner_path** (*str*) – The path to a saved Learner instance file.

• **logger** (*logging object, optional*) – A logging object. If None is passed, get logger from __name__. Defaults to None.

**Returns** *learner* – The Learner instance loaded from the file.

**Return type** `skll.Learner`

**Raises**

• `ValueError` – If the pickled object is not a Learner instance.
- ValueError – If the pickled version of the Learner instance is out of date.

**learning_curve** *(examples, metric, cv_folds=10, train_sizes=array([0.1, 0.325, 0.55, 0.775, 1.]))*

Generates learning curves for a given model on the training examples via cross-validation. Adapted from the scikit-learn code for learning curve generation (cf.``sklearn.model_selection.learning_curve``).

**Parameters**

- **examples** *(skll.FeatureSet)* – The FeatureSet instance to generate the learning curve on.
- **cv_folds** *(int, optional)* – The number of folds to use for cross-validation, or a mapping from example IDs to folds. Defaults to 10.
- **metric** *(str)* – The name of the metric function to use when computing the train and test scores for the learning curve.
- **train_sizes** *(list of float or int, optional)* – Relative or absolute numbers of training examples that will be used to generate the learning curve. If the type is float, it is regarded as a fraction of the maximum size of the training set (that is determined by the selected validation method), i.e. it has to be within (0, 1]. Otherwise it is interpreted as absolute sizes of the training sets. Note that for classification the number of samples usually have to be big enough to contain at least one sample from each class. Defaults to `np.linspace(0.1, 1.0, 5)`.

**Returns**

- **train_scores** *(list of float)* – The scores for the training set.
- **test_scores** *(list of float)* – The scores on the test set.
- **num_examples** *(list of int)* – The numbers of training examples used to generate the curve

**load** *(learner_path)*

Replace the current learner instance with a saved learner.

**Parameters** **learner_path** *(str)* – The path to a saved learner object file to load.

**model**

The underlying scikit-learn model

**model_kwargs**

A dictionary of the underlying scikit-learn model’s keyword arguments
model_params
Model parameters (i.e., weights) for a LinearModel (e.g., Ridge) regression and liblinear models. If the model was trained using feature hashing, then names of the form hashed_feature_XX are used instead.

Returns
- res (dict) – A dictionary of labeled weights.
- intercept (dict) – A dictionary of intercept(s).

Raises ValueError – If the instance does not support model parameters.

model_type
The model type (i.e., the class)

predict (examples, prediction_prefix=None, append=False, class_labels=False)
Uses a given model to generate predictions on a given FeatureSet.

Parameters
- examples (skll.FeatureSet) – The FeatureSet instance to predict labels for.
- prediction_prefix (str, optional) – If saving the predictions, this is the prefix that will be used for the filename. It will be followed by "_predictions.tsv" Defaults to None.
- append (bool, optional) – Should we append the current predictions to the file if it exists? Defaults to False.
- class_labels (bool, optional) – For classifier, should we convert class indices to their (str) labels for the returned array? Note that class labels are always written out to disk. Defaults to False.

Returns yhat – The predictions returned by the Learner instance.

Return type array-like

Raises MemoryError – If process runs out of memory when converting to dense.

probability
Should learner return probabilities of all labels (instead of just label with highest probability)?

save (learner_path)
Save the Learner instance to a file.

Parameters learner_path (str) – The path to save the Learner instance to.
`train` *(examples, param_grid=None, grid_search_folds=3, grid_search=True, grid_objective=None, grid_jobs=None, shuffle=False, create_label_dict=True)*

Train a classification model and return the model, score, feature vectorizer, scaler, label dictionary, and inverse label dictionary.

**Parameters**

- **examples** *(skll.FeatureSet)* – The FeatureSet instance to use for training.
- **param_grid** *(list of dicts, optional)* – The parameter grid to search through for grid search. If None, a default parameter grid will be used. Defaults to None.
- **grid_search_folds** *(int or dict, optional)* – The number of folds to use when doing the grid search, or a mapping from example IDs to folds. Defaults to 3.
- **grid_search** *(bool, optional)* – Should we do grid search? Defaults to True.
- **grid_objective** *(str, optional)* – The name of the objective function to use when doing the grid search. Must be specified if `grid_search` is True. Defaults to None.
- **grid_jobs** *(int, optional)* – The number of jobs to run in parallel when doing the grid search. If None or 0, the number of grid search folds will be used. Defaults to None.
- **shuffle** *(bool, optional)* – Shuffle examples (e.g., for grid search CV.) Defaults to False.
- **create_label_dict** *(bool, optional)* – Should we create the label dictionary? This dictionary is used to map between string labels and their corresponding numerical values. This should only be done once per experiment, so when `cross_validate` calls `train`, `create_label_dict` gets set to False. This option is only for internal use. Defaults to True.

**Returns** tuple – 1) The best grid search objective function score, or 0 if we’re not doing grid search, and 2) a dictionary of grid search CV results with keys such as “params”, “mean_test_score”, etc, that are mapped to lists of values associated with each hyperparameter set combination, or None if not doing grid search.

**Return type** (float, dict)

**Raises**
• ValueError – If grid_objective is not a valid grid objective or if one is not specified when necessary.
• MemoryError – If process runs out of memory converting training data to dense.
• ValueError – If FeatureHasher is used with MultinomialNB.

class skll.learner.RescaledAdaBoostRegressor (base_estimator=None,
    n_estimators=50,
    learning_rate=1.0,
    loss='linear',  random_state=None)

Bases: sklearn.ensemble._weight_boosting.AdaBoostRegressor

fit (X, y, sample_weight=None)
Build a boosted regressor from the training set (X, y).

Parameters

• X 
(array-like, sparse matrix) of shape (n_samples, n_features) – The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

• y (array-like of shape (n_samples,)) – The target values (real numbers).

• sample_weight (array-like of shape (n_samples,),
  default=None) – Sample weights. If None, the sample weights are initialized to 1 / n_samples.

Returns self

Return type object

predict (X)
Predict regression value for X.

The predicted regression value of an input sample is computed as the weighted median prediction of the classifiers in the ensemble.

Parameters X 
(array-like, sparse matrix) of shape (n_samples, n_features) – The training input samples. Sparse matrix can be CSC, CSR, COO, DOK, or LIL. COO, DOK, and LIL are converted to CSR.

Returns y – The predicted regression values.

Return type ndarray of shape (n_samples,)
class skll.learner.RescaledBayesianRidge(n_iter=300, tol=0.001, alpha_1=1e-06, alpha_2=1e-06, lambda_1=1e-06, lambda_2=1e-06, alpha_init=None, lambda_init=None, compute_score=False, fit_intercept=True, normalize=False, copy_X=True, verbose=False)

Bases: sklearn.linear_model._bayes.BayesianRidge

fit (X, y, sample_weight=None)
Fit the model

Parameters

- X (ndarray of shape (n_samples, n_features)) – Training data
- y (ndarray of shape (n_samples,)) – Target values. Will be cast to X’s dtype if necessary
- sample_weight (ndarray of shape (n_samples,), default=None) – Individual weights for each sample

Returns self

Return type returns an instance of self.

predict (X, return_std=False)
Predict using the linear model.

In addition to the mean of the predictive distribution, also its standard deviation can be returned.

Parameters

- X ((array-like, sparse matrix) of shape (n_samples, n_features)) – Samples.
- return_std (bool, default=False) – Whether to return the standard deviation of posterior prediction.

Returns

- y_mean (array-like of shape (n_samples,)) – Mean of predictive distribution of query points.
• **y_std** *(array-like of shape (n_samples,)) – Standard deviation of predictive distribution of query points.*

class skll.learner.RescaledDecisionTreeRegressor *(criterion='mse', splitter='best', max_depth=None, min_samples_split=2, min_samples_leaf=1, min_weight_fraction_leaf=0.0, max_features=None, random_state=None, max_leaf_nodes=None, min_impurity_decrease=0.0, min_impurity_split=None, pre_sort='deprecated', ccp_alpha=0.0)*

Bases: sklearn.tree._classes.DecisionTreeRegressor

**fit** *(X, y, sample_weight=None, check_input=True, X_idx_sorted=None)*

Build a decision tree regressor from the training set \((X, y)\).

**Parameters**

- **X** *(array-like, sparse matrix) of shape \((n_samples, n_features)\) – The training input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csc_matrix.*

- **y** *(array-like of shape \((n_samples,\)) or \((n_samples, n_outputs)\) – The target values (real numbers). Use dtype=np.float64 and order='C' for maximum efficiency.*

- **sample_weight** *(array-like of shape \((n_samples,\)), default=None) – Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node.*

- **check_input** *(bool, default=True) – Allow to bypass several input checking. Don’t use this parameter unless you know what you do.*

- **X_idx_sorted** *(array-like of shape \((n_samples, n_features), default=None) – The indexes of the sorted training input samples. If many tree are grown on the same dataset, this allows the ordering to be cached between trees. If None, the data
will be sorted here. Don’t use this parameter unless you know what to do.

**Returns**  
self – Fitted estimator.

**Return type**  
DecisionTreeRegressor

### predict \( (X, check\_input=True) \)

Predict class or regression value for \( X \).

For a classification model, the predicted class for each sample in \( X \) is returned. For a regression model, the predicted value based on \( X \) is returned.

**Parameters**

- \( X \)  
  (array-like, sparse matrix) of shape (n_samples, n_features) – The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

- \( check\_input \) (bool, default=True) – Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

**Returns**  
y – The predicted classes, or the predict values.

**Return type**  
array-like of shape (n_samples,) or (n_samples, n_outputs)

### class skll.learner.RescaledElasticNet \( (alpha=1.0, \quad ll\_ratio=0.5, \quad fit\_intercept=True, \quad normalize=False, \quad precompute=False, \quad max\_iter=1000, \quad copy\_X=True, \quad tol=0.0001, \quad warm\_start=False, \quad positive=False, \quad random\_state=None, \quad selection='cyclic') \)

Bases: sklearn.linear_model._coordinate_descent.ElasticNet

### fit \( (X, y, check\_input=True) \)

Fit model with coordinate descent.

**Parameters**

- \( X \)  
  (ndarray or scipy.sparse matrix, (n_samples, n_features)) – Data

- \( y \)  
  (ndarray, shape (n_samples,) or (n_samples, n_targets)) – Target. Will be cast to X’s dtype if necessary

- \( check\_input \) (boolean, (default=True)) – Allow to bypass several input checking. Don’t use this parameter unless you know what you do.
Notes

Coordinate descent is an algorithm that considers each column of data at a time hence it will automatically convert the X input as a Fortran-contiguous numpy array if necessary.

To avoid memory re-allocation it is advised to allocate the initial data in memory directly using that format.

`predict(X)`

Predict using the linear model.

**Parameters**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>X</strong></td>
<td>array_like or sparse matrix, shape (n_samples, n_features) – Samples.</td>
</tr>
</tbody>
</table>

**Returns**

C – Returns predicted values.

**Return type**

array, shape (n_samples,)

class skll.learner.RescaledGradientBoostingRegressor(loss='ls',
learning_rate=0.1,
n_estimators=100,
subsample=1.0,
criterion='friedman_mse',
min_samples_split=2,
min_samples_leaf=1,
min_weight_fraction_leaf=0.0,
max_depth=3,
min_impurity_decrease=0.0,
min_impurity_split=None,
init=None,
random_state=None,
max_features=None,
alpha=0.9,
verbose=0,
max_leaf_nodes=None,
warm_start=False,
pre_sort='deprecated',
validation_fraction=0.1,
n_iter_no_change=None,
tol=0.0001,
ccp_alpha=0.0)
Bases: sklearn.ensemble._gb.GradientBoostingRegressor

**fit** *(X, y, sample_weight=None, monitor=None)*

Fit the gradient boosting model.

**Parameters**

- **X** *(array-like, sparse matrix), shape (n_samples, n_features)* – The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

- **y** *(array-like, shape (n_samples,)) – Target values (strings or integers in classification, real numbers in regression) For classification, labels must correspond to classes.

- **sample_weight** *(array-like, shape (n_samples,) or None) – Sample weights. If None, then samples are equally weighted. Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node. In the case of classification, splits are also ignored if they would result in any single class carrying a negative weight in either child node.

- **monitor** *(callable, optional) – The monitor is called after each iteration with the current iteration, a reference to the estimator and the local variables of _fit_stages as keyword arguments callable(i, self, locals()). If the callable returns True the fitting procedure is stopped. The monitor can be used for various things such as computing held-out estimates, early stopping, model introspect, and snapshoting.*

**Returns** *self*

**Return type** *object*

**predict** *(X)*

Predict regression target for X.

**Parameters** **X** *(array-like, sparse matrix), shape (n_samples, n_features)* – The input samples. Internally, it will be converted to dtype=np.float32 and if a sparse matrix is provided to a sparse csr_matrix.

**Returns** **y** – The predicted values.

**Return type** *array, shape (n_samples,)*
class skll.learner.RescaledHuberRegressor (epsilon=1.35, max_iter=100, alpha=0.0001, warm_start=False, fit_intercept=True, tol=1e-05)

Bases: sklearn.linear_model._huber.HuberRegressor

fit (X, y, sample_weight=None)
Fit the model according to the given training data.

Parameters

• X (array-like, shape (n_samples, n_features)) – Training vector, where n_samples is the number of samples and n_features is the number of features.

• y (array-like, shape (n_samples,)) – Target vector relative to X.

• sample_weight (array-like, shape (n_samples,)) – Weight given to each sample.

Returns self
Return type object

predict (X)
Predict using the linear model.

Parameters X (array-like or sparse matrix, shape (n_samples, n_features)) – Samples.

Returns C – Returns predicted values.
Return type array, shape (n_samples,)

class skll.learner.RescaledKNeighborsRegressor (n_neighbors=5, weights='uniform', algorithm='auto', leaf_size=30, p=2, metric='minkowski', metric_params=None, n_jobs=None, **kwargs)

Bases: sklearn.neighbors._regression.KNeighborsRegressor

fit (X, y)
Fit the model using X as training data and y as target values

Parameters
• **X** ({array-like, sparse matrix, BallTree, KDTree}) – Training data. If array or matrix, shape [n_samples, n_features], or [n_samples, n_samples] if metric='precomputed'.

• **y** (array-like, sparse matrix) – Target values, array of float values, shape = [n_samples] or [n_samples, n_outputs]

**predict** *(X)*

Predict the target for the provided data

**Parameters**

**X** (array-like, shape (n_samples, n_features), or (n_samples, n_indexed) if metric = 'precomputed') – Test samples.

**Returns**

**y** – Target values

**Return type** array of int, shape = [n_queries] or [n_queries, n_outputs]

**class** skll.learner.RescaledLars *(fit_intercept=True, verbose=False, normalize=True, precompute='auto', n_nonzero_coefs=500, eps=2.220446049250313e-16, copy_X=True, fit_path=True)*

Bases: sklearn.linear_model._least_angle.Lars

**fit** *(X, y, Xy=None)*

Fit the model using X, y as training data.

**Parameters**

• **X** (array-like of shape (n_samples, n_features)) – Training data.

• **y** (array-like of shape (n_samples,) or (n_samples, n_targets)) – Target values.

• **Xy** (array-like of shape (n_samples,) or (n_samples, n_targets), default=None) – Xy = np.dot(X.T, y) that can be precomputed. It is useful only when the Gram matrix is precomputed.

**Returns**

**self** – returns an instance of self.

**Return type** object

**predict** *(X)*

Predict using the linear model.

**Parameters**

**X** (array-like or sparse matrix, shape (n_samples, n_features)) – Samples.
Returns C – Returns predicted values.

Return type array, shape (n_samples,)

class skll.learner.RescaledLasso(alpha=1.0, fit_intercept=True, normalize=False, precompute=False, copy_X=True, max_iter=1000, tol=0.0001, warm_start=False, positive=False, random_state=None, selection='cyclic')

Bases: sklearn.linear_model._coordinate_descent.Lasso

fit (X, y, check_input=True)

Fit model with coordinate descent.

Parameters

• X (ndarray or scipy.sparse matrix, (n_samples, n_features)) – Data

• y (ndarray, shape (n_samples,) or (n_samples, n_targets)) – Target. Will be cast to X’s dtype if necessary

• check_input (boolean, (default=True)) – Allow to bypass several input checking. Don’t use this parameter unless you know what you do.

Notes

Coordinate descent is an algorithm that considers each column of data at a time hence it will automatically convert the X input as a Fortran-contiguous numpy array if necessary.

To avoid memory re-allocation it is advised to allocate the initial data in memory directly using that format.

predict (X)

Predict using the linear model.

Parameters X (array_like or sparse matrix, shape (n_samples, n_features)) – Samples.

Returns C – Returns predicted values.

Return type array, shape (n_samples,)

class skll.learner.RescaledLinearRegression (fit_intercept=True, normalize=False, copy_X=True, n_jobs=None)

Bases: sklearn.linear_model._base.LinearRegression
**fit** *(X, y, sample_weight=None)*

Fit linear model.

**Parameters**

- **X** *(array-like, sparse matrix) of shape (n_samples, n_features)* – Training data
- **y** *(array-like of shape (n_samples,)) or (n_samples, n_targets)* – Target values. Will be cast to X’s dtype if necessary
- **sample_weight** *(array-like of shape (n_samples,), default=None)* – Individual weights for each sample

New in version 0.17: parameter *sample_weight* support to Linear-Regression.

**Returns** *self*

**Return type** returns an instance of self.

**predict** *(X)*

Predict using the linear model.

**Parameters** **X** *(array-like or sparse matrix, shape (n_samples, n_features))* – Samples.

**Returns** *C* – Returns predicted values.

**Return type** array, shape (n_samples,)

**class** `skll.learner.RescaledLinearSVR` *(epsilon=0.0, tol=0.0001, C=1.0, loss='epsilon_insensitive', fit_intercept=True, intercept_scaling=1.0, dual=True, verbose=0, random_state=None, max_iter=1000)*

**Bases** `sklearn.svm._classes.LinearSVR`

**fit** *(X, y, sample_weight=None)*

Fit the model according to the given training data.

**Parameters**

- **X** *(array-like, sparse matrix) of shape (n_samples, n_features)) – Training vector, where n_samples in the number of samples and n_features is the number of features.
- **y** *(array-like of shape (n_samples,)) – Target vector relative to X*
• **sample_weight** *(array-like of shape (n_samples,), default=None)* – Array of weights that are assigned to individual samples. If not provided, then each sample is given unit weight.

Returns self

Return type object

```{.method}

predict (X)
```

Predict using the linear model.

**Parameters**

* X *(array_like or sparse matrix, shape (n_samples, n_features))* – Samples.

**Returns**

* C – Returns predicted values.

**Return type**

array, shape (n_samples,)

```{.class}

class skll.learner.RescaledMLPRegressor (hidden_layer_sizes=(100, ), activation='relu', solver='adam', alpha=0.0001, batch_size='auto', learning_rate='constant', learning_rate_init=0.001, power_t=0.5, max_iter=200, shuffle=True, random_state=None, tol=0.0001, verbose=False, warm_start=False, momentum=0.9, nesterovs_momentum=True, early_stopping=False, validation_fraction=0.1, beta_1=0.9, beta_2=0.999, epsilon=1e-08, n_iter_no_change=10, max_fun=15000)
```

Bases:

`sklearn.neural_network._multilayer_perceptron.MLPRegressor`

```{.method}

fit (X, y)
```

Fit the model to data matrix X and target(s) y.

**Parameters**

* X *(ndarray or sparse matrix of shape (n_samples, n_features))* – The input data.

* y *(ndarray of shape (n_samples,) or (n_samples, n_outputs))* – The target values (class labels in classification, real numbers in regression).
Returns self

Return type returns a trained MLP model.

predict (X)
Predict using the multi-layer perceptron model.

Parameters

\(X\) \((\text{array-like, sparse matrix})\text{ of shape (n_samples, n_features))}\) – The input data.

Returns \(y\) – The predicted values.

Return type ndarray of shape (n_samples, n_outputs)

class skll.learner.RescaledRANSACRegressor (base_estimator=None, min_samples=None, residual_threshold=None, is_data_valid=None, is_model_valid=None, max_trials=100, max_skips=inf, stop_n_inliers=inf, stop_score=inf, stop_probability=0.99, loss='absolute_loss', random_state=None)

Bases: sklearn.linear_model._ransac.RANSACRegressor

fit (X, y, sample_weight=None)
Fit estimator using RANSAC algorithm.

Parameters

\(X\) \((\text{array-like or sparse matrix, shape [n_samples, n_features])}\) – Training data.

\(y\) \((\text{array-like of shape (n_samples,) or (n_samples, n_targets))}\) – Target values.

\(\text{sample_weight}\) \((\text{array-like of shape (n_samples,)}, \text{default=None})\) – Individual weights for each sample raises error if sample_weight is passed and base_estimator fit method does not support it.

Raises ValueError – If no valid consensus set could be found. This occurs if is_data_valid and is_model_valid return False for all max_trials randomly chosen sub-samples.

predict (X)
Predict using the estimated model.

This is a wrapper for estimator_.predict(X).
Parameters

\textbf{X} \hspace{1cm} (\text{numpy array of shape [n\_samples, n\_features]})

\textbf{Returns} \; y \rightarrow \text{Returns predicted values.}

\textbf{Return type} \; \text{array, shape = [n\_samples] or [n\_samples, n\_targets]}

class \text{skll\_learner.\textit{RescaledRandomForestRegressor}}(\text{n\_estimators=100, criterion='mse',
max\_depth=None, min\_samples\_split=2, min\_samples\_leaf=1, min\_weight\_fraction\_leaf=0.0,
max\_features='auto', max\_leaf\_nodes=None, min\_impurity\_decrease=0.0, min\_impurity\_split=None,
bootstrap=True, oob\_score=False, n\_jobs=None, random\_state=None, verbose=0,
warm\_start=False, ccp\_alpha=0.0, max\_samples=None))

Bases: \text{sklearn.ensemble._forest.RandomForestRegressor}

\textbf{fit} (X, y, sample\_weight=None)

\text{Build a forest of trees from the training set (X, y).}

\textbf{Parameters}

\begin{itemize}
  \item \textbf{X} \hspace{1cm} (array-like or sparse matrix of shape (n\_samples, n\_features)) \rightarrow \text{The training input samples.} 
  \hspace{1cm} \text{Internally, its dtype will be converted to dtype=np.float32.}
  \hspace{1cm} \text{If a sparse matrix is provided, it will be converted into a sparse csc\_matrix.}

  \item \textbf{y} \hspace{1cm} (array-like of shape (n\_samples,) or (n\_samples, n\_outputs)) \rightarrow \text{The target values (class labels in classification, real numbers in regression).}

  \item \textbf{sample\_weight} (array-like of shape (n\_samples,), default=None) \rightarrow \text{Sample weights. If None, then samples are equally weighted.}
  \hspace{1cm} \text{Splits that would create child nodes with net zero or negative weight are ignored while searching for a split in each node.}
  \hspace{1cm} \text{In the case of classification, splits are also ignored if they would result in any single class carrying a negative weight in either child node.}
\end{itemize}
**predict (X)**
Predict regression target for X.

The predicted regression target of an input sample is computed as the mean predicted regression targets of the trees in the forest.

**Parameters**

- **X** *(array-like or sparse matrix of shape (n_samples, n_features)) – The input samples. Internally, its dtype will be converted to dtype=np.float32. If a sparse matrix is provided, it will be converted into a sparse csr_matrix.*

**Returns**

- **y** – The predicted values.

**Return type** array-like of shape (n_samples,) or (n_samples, n_outputs)

class skll.learner.RescaledRidge(
    alpha=1.0,  
    fit_intercept=True,  
    normalize=False,  
    copy_X=True,  
    max_iter=None,  
    tol=0.001,  
    solver='auto',  
    random_state=None
)

**fit (X, y, sample_weight=None)**
Fit Ridge regression model.

**Parameters**

- **X** *(ndarray, sparse matrix) of shape (n_samples, n_features)) – Training data*

- **y** *(ndarray of shape (n_samples,) or (n_samples, n_targets)) – Target values*

- **sample_weight** *(float or ndarray of shape (n_samples,), default=None) – Individual weights for each sample. If given a float, every sample will have the same weight.*

**Returns**

- **self**

**Return type** returns an instance of self.

**predict (X)**
Predict using the linear model.

**Parameters**

- **X** *(array_like or sparse matrix, shape (n_samples, n_features)) – Samples.*

**Returns**

- **C** – Returns predicted values.

**Return type** array, shape (n_samples,)
class skll.learner.RescaledSGDRegressor (loss='squared_loss',
    penalty='l2', alpha=0.0001, l1_ratio=0.15,
    fit_intercept=True, max_iter=1000, tol=0.001,
    shuffle=True, verbose=0, epsilon=0.1, random_state=None,
    learning_rate='invscaling', eta0=0.01, power_t=0.25,
    early_stopping=False, validation_fraction=0.1,
    n_iter_no_change=5, warm_start=False, average=False)

Bases: sklearn.linear_model._stochastic_gradient.SGDRegressor

fit (X, y, coef_init=None, intercept_init=None, sample_weight=None)
Fit linear model with Stochastic Gradient Descent.

Parameters

• X (array-like, sparse matrix), shape (n_samples, n_features) – Training data

• y (ndarray of shape (n_samples,)) – Target values

• coef_init (ndarray of shape (n_features,), default=None) – The initial coefficients to warm-start the optimization.

• intercept_init (ndarray of shape (1,), default=None) – The initial intercept to warm-start the optimization.

• sample_weight (array-like, shape (n_samples,), default=None) – Weights applied to individual samples (1. for unweighted).

Returns self

Return type returns an instance of self.

predict (X)
Predict using the linear model

Parameters X (array-like, sparse matrix), shape (n_samples, n_features)–

Returns Predicted target values per element in X.
**class** scikit.learner.RescaledSVR

```
RescaledSVR(kernel='rbf', degree=3, gamma='scale',
            coef0=0.0, tol=0.001, C=1.0, epsilon=0.1,
            shrinking=True, cache_size=200, verbose=False, max_iter=-1)
```

**Bases:** sklearn.svm._classes.SVR

**fit** (X, y, sample_weight=None)

Fit the SVM model according to the given training data.

**Parameters**

- **X**
  - (array-like, sparse matrix), shape (n_samples, n_features) – Training vectors, where n_samples is the number of samples and n_features is the number of features. For kernel=“precomputed”, the expected shape of X is (n_samples, n_samples).

- **y**
  - (array-like, shape (n_samples,)) – Target values (class labels in classification, real numbers in regression)

- **sample_weight**
  - (array-like, shape (n_samples,)) – Per-sample weights. Rescale C per sample. Higher weights force the classifier to put more emphasis on these points.

**Returns**

- **self**

**predict** (X)

Perform regression on samples in X.

For an one-class model, +1 (inlier) or -1 (outlier) is returned.

**Parameters**

- **X**
  - (array-like, sparse matrix), shape (n_samples, n_features) – For kernel=“precomputed”, the expected shape of X is (n_samples_test, n_samples_train).

**Returns**

- **y_pred**

**Return type**

- array, shape (n_samples,)
class skll.learner.RescaledTheilSenRegressor (fit_intercept=True,
copy_X=True,
max_subpopulation=10000.0,
n_subsamples=None,
max_iter=300,
tol=0.001, random_state=None,
n_jobs=None,
verbose=False)

Bases: sklearn.linear_model._theil_sen.TheilSenRegressor

fit (X, y)
Fit linear model.

Parameters

• X (numpy array of shape [n_samples, n_features])
  – Training data

• y (numpy array of shape [n_samples]) – Target values

Returns self

Return type returns an instance of self.

predict (X)
Predict using the linear model.

Parameters X (array_like or sparse matrix, shape
(n_samples, n_features)) – Samples.

Returns C – Returns predicted values.

Return type array, shape (n_samples,)

class skll.learner.SelectByMinCount (min_count=1)
Bases: sklearn.feature_selection._univariate_selection.SelectKBest

Select features occurring in more (and/or fewer than) than a specified number of examples in the training data (or a CV training fold).

Parameters min_count (int, optional) – The minimum feature count to select. Defaults to 1.

fit (X, y=None)
Fit the SelectByMinCount model.

Parameters

• X (array-like, with shape (n_samples, n_features)) – The training data to fit.
• y (Ignored) –

Returns

Return type self

skll.learner.rescaled(cls)

Decorator to create regressors that store a min and a max for the training data and make sure
that predictions fall within that range. It also stores the means and SDs of the gold standard
and the predictions on the training set to rescale the predictions (e.g., as in e-rater).

Parameters cls (BaseEstimator) – An estimator class to add rescaling to.

Returns cls – Modified version of estimator class with rescaled functions added.

Return type BaseEstimator

Raises ValueError – If classifier cannot be rescaled (i.e. is not a regressor).

1.6.6 metrics Module

This module contains a bunch of evaluation metrics that can be used to evaluate the performance
of learners.

author Michael Heilman (mheilman@ets.org)

author Nitin Madnani (nmadnani@ets.org)

author Dan Blanchard (dblanchard@ets.org)

organization ETS

skll.metrics.correlation (y_true, y_pred, corr_type='pearson')

Calculate given correlation between y_true and y_pred. y_pred can be multi-
dimensional. If y_pred is 1-dimensional, it may either contain probabilities, most-likely
classification labels, or regressor predictions. In that case, we simply return the correlation
between y_true and y_pred. If y_pred is multi-dimensional, it contains probabilities
for multiple classes in which case, we infer the most likely labels and then compute the
correlation between those and y_true.

Parameters

• y_true (array-like of float) – The true/actual/gold labels for
  the data.

• y_pred (array-like of float) – The predicted/observed labels
  for the data.

• corr_type (str, optional) – Which type of correlation to com-
  pute. Possible choices are pearson, spearman, and kendall_tau.
  Defaults to pearson.
Returns `ret_score` – correlation value if well-defined, else 0.0

Return type float

`skll.metrics.f1_score_least_frequent(y_true, y_pred)`

Calculate the F1 score of the least frequent label/class in `y_true` for `y_pred`.

Parameters

- `y_true` (array-like of float) – The true/actual/gold labels for the data.
- `y_pred` (array-like of float) – The predicted/observed labels for the data.

Returns `ret_score` – F1 score of the least frequent label.

Return type float

`skll.metrics.kappa(y_true, y_pred, weights=None, allow_off_by_one=False)`

Calculates the kappa inter-rater agreement between two the gold standard and the predicted ratings. Potential values range from -1 (representing complete disagreement) to 1 (representing complete agreement). A kappa value of 0 is expected if all agreement is due to chance.

In the course of calculating kappa, all items in `y_true` and `y_pred` will first be converted to floats and then rounded to integers.

It is assumed that `y_true` and `y_pred` contain the complete range of possible ratings.

This function contains a combination of code from yorchopolis’s kappa-stats and Ben Hamner’s Metrics projects on Github.

Parameters

- `y_true` (array-like of float) – The true/actual/gold labels for the data.
- `y_pred` (array-like of float) – The predicted/observed labels for the data.
- `weights` (str or np.array, optional) – Specifies the weight matrix for the calculation. Options are
  - `None` = unweighted-kappa
  - `'quadratic'` = quadratic-weighted kappa
  - `'linear'` = linear-weighted kappa
  - two-dimensional numpy array = a custom matrix of weights. Each weight corresponds to the $w_{ij}$ values in the wikipedia description of how to calculate weighted Cohen’s kappa. Defaults to None.
• **allow_off_by_one**(bool, optional) – If true, ratings that are off by one are counted as equal, and all other differences are reduced by one. For example, 1 and 2 will be considered to be equal, whereas 1 and 3 will have a difference of 1 for when building the weights matrix. Defaults to False.

**Returns** k – The kappa score, or weighted kappa score.

**Return type** float

**Raises**

- AssertionError – If y_true != y_pred.
- ValueError – If labels cannot be converted to int.
- ValueError – If invalid weight scheme.

skll.metrics.use_score_func(func_name, y_true, y_pred)

Call the scoring function in sklearn.metrics.SCORERS with the given name. This takes care of handling keyword arguments that were pre-specified when creating the scorer. This applies any sign-flipping that was specified by make_scorer() when the scorer was created.

**Parameters**

- **func_name**(str) – The name of the objective function to use from SCORERS.
- **y_true**(array-like of float) – The true/actual/gold labels for the data.
- **y_pred**(array-like of float) – The predicted/observed labels for the data.

**Returns** ret_score – The scored result from the given scorer.

**Return type** float

## 1.7 Contributing

Thank you for your interest in contributing to SKLL! We welcome any and all contributions.

### 1.7.1 Guidelines

The SKLL contribution guidelines can be found in our Github repository [here](#). Please try to follow them as much as possible.
1.7.2 SKLL Code Overview

This section will help you get oriented with the SKLL codebase by describing how it is organized, the various SKLL entry points into the code, and what the general code flow looks like for each entry point.

Organization

The main Python code for the SKLL package lives inside the skll sub-directory of the repository. It contains the following files and sub-directories:

- __init__.py : Code used to initialize the skll Python package.
- config.py : Code to parse SKLL experiment configuration files.
- experiments.py : Code that is related to creating and running SKLL experiments. It also contains code that collects the various evaluation metrics and predictions for each SKLL experiment and writes them out to disk.
- learner.py : Code for the Learner class. This class is instantiated for every learner name specified in the experiment configuration file.
- metrics.py : Code for any custom metrics that are not in sklearn.metrics, e.g., kappa, kendall_tau, spearman, etc.
- logutils.py : Code for a custom logging solution that allows capturing any information logged to STDOUT/STDERR by SKLL and scikit-learn to also be captured into log files that are then saved on disk.
- version.py : Code to define the SKLL version. Only changed for new releases.
- data/
  - __init__.py : Code used to initialize the skll.data Python package.
  - featureset.py : Code for the FeatureSet class – the main class that encapsulates all of the features names, values, and metadata for a given set of instances.
  - readers.py : Code for classes that can read various file formats and create FeatureSet objects from them.
  - writers.py : Code for classes that can write FeatureSet objects to files on disk in various formats.
  - dict_vectorizer.py : Code for a DictVectorizer class that subclasses sklearn.feature_extraction.DictVectorizer to add an __eq__() method that we need for vectorizer equality.
- utilities/
  - compute_eval_from_predictions.py : See documentation.
– filter_features.py : See documentation.
– generate_predictions.py : See documentation.
– join_features.py : See documentation.
– plot_learning_curves.py : See documentation.
– print_model_weights.py : See documentation.
– run_experiment.py : See documentation.
– skll_convert.py : See documentation.
– summarize_results.py : See documentation.

• tests/
  – test_*_.py : These files contain the code for the unit tests and regression tests.

**Entry Points & Workflow**

There are three main entry points into the SKLL codebase:

1. **Experiment configuration files.** The primary way to interact with SKLL is by writing configuration files and then passing it to the run_experiment script. When you run the command `run_experiment <config_file>`, the following happens (at a high level):
   - the configuration file is handed off to the run_configuration() function in experiments.py.
   - a SKLLConfigParser object is instantiated from config.py that parses all of the relevant fields out of the given configuration file.
   - the configuration fields are then passed to the _classify_featureset() function in experiments.py which instantiates the learners (using code from learner.py), the featuresets (using code from reader.py & featureset.py), and runs the experiments, collects the results, and writes them out to disk.

2. **SKLL API.** Another way to interact with SKLL is via the SKLL API directly in your Python code rather than using configuration files. For example, you could use the Learner.from_file() method to load a saved model from disk and make predictions on new data. The documentation for the SKLL API can be found [here](#).

3. **Utility scripts.** The scripts listed in the section above under utilities are also entry points into the SKLL code. These scripts are convenient wrappers that use the SKLL API for commonly used tasks, e.g., generating predictions on new data from an already trained model.
1.8 Internal Documentation

1.8.1 Release Process

This document is only meant for the project administrators, not users and developers.

1. Create a release branch release/XX on GitHub.

2. In the release branch:
   a. update the version numbers in version.py.
   b. update the conda recipe.
   c. update the documentation with any new features or details about changes.
   d. run make linkcheck on the documentation and fix any redirected/broken links.
   e. update the README and this release documentation, if necessary.

3. Run the following command in the conda-recipe directory to build the conda package:

   ```bash
   conda build -c conda-forge --numpy=1.17 .
   ```

4. Upload the package to anaconda.org using anaconda upload --user ets <package tarball>. You will need to have the appropriate permissions for the ets organization.

5. Build the PyPI source distribution using python setup.py sdist build.

6. Upload the source distribution to TestPyPI using twine upload --repository testpypi dist/*. You will need to have the twine package installed and set up your $HOME/.pypirc correctly. See details here.

7. Test the conda package by creating a new environment on different platforms with this package installed and then running SKLL examples or tests from a SKLL working copy. If the package works, then move on to the next step. If it doesn’t, figure out why and rebuild and re-upload the package.

8. Test the TestPyPI package by installing it as follows:

   ```bash
   pip install --index-url https://test.pypi.org/simple/ --extra-index-url https://pypi.org/simple skll
   ```

9. Then run some SKLL examples or tests from a SKLL working copy. If the TestPyPI package works, then move on to the next step. If it doesn’t, figure out why and rebuild and re-upload the package.

10. Create pull requests on the skill-conda-tester and skill-pip-tester repositories to test the conda and TestPyPI packages on Linux and Windows.
11. Draft a release on GitHub while the Linux and Windows package tester builds are running.

12. Once both builds have passed, make a pull request with the release branch to be merged into master and request code review.

13. Once the build for the PR passes and the reviewers approve, merge the release branch into master.

14. Upload source and wheel packages to PyPI using `python setup.py sdist upload` and `python setup.py bdist_wheel upload`

15. Make sure that the ReadTheDocs build for master passes.

16. Tag the latest commit in master with the appropriate release tag and publish the release on GitHub.

17. Send an email around at ETS announcing the release and the changes.

18. Post release announcement on Twitter/LinkedIn.
